New Laboratory Building Nears Completion.—The new south laboratory building on the campus of the University of Nebraska College of Medicine at Omaha is rapidly being completed and will be ready for the opening of the fall session in September. The new building will house the departments of biological chemistry, physiology and pharmacology, as well as the university outpatient department and the department of experimental surgery. The north laboratory building completed in 1913 houses the laboratories of anatomy, including histology and embryology, pathology and bacteriology. Between the two laboratory buildings but further in the background is the University Hospital completed in 1917 which has 130 teaching beds. These three buildings, which are uniformly four stories in height and of uniform construction, were erected at a cost of over \$500,000. The campus is large enough to provide space for other laboratory buildings or hospitals which the future may demand. The University of Nebraska College of Medicine represents one of the many marvels of growth among medical schools in the United States since all building construction at Omaha has been done during the last six years.

PENNSYLVANIA

State Society Meeting.—The annual meeting of the Medical Society of the State of Pennsylvania will be held in Harrisburg, September 23 to 26, under the presidency of Dr. Frederick L. Van Sickle, Olyphant.

Personal.—George W. Stimson, Major, M. C., U. S. Army, Pittsburgh, who has been serving in France as otolaryngologist with Evacuation Hospital No. 31, landed in Newport News, Va., July 20.—Dr. Thomas D. White, Orrstown, has been elected chief of staff and Dr. Joseph J. Maclay, Chambersburg, reelected secretary-treasurer of the staff of the Chambersburg Hospital.—Dr. Julius H. Conroe, York, has been appointed chief of the York Genito-Urinary Dispensary; Dr. Chester G. Crist, Gettysburg, medical inspector for Adams County, and Dr. James P. Dalbey, Gettysburg, narcotic inspector for Cumberland and Adams counties.

Philadelphia

Personal.—Dr. Samuel T. Orton of the University of Pennsylvania Hospital has been appointed head of the Psychopathic Hospital of the University of Iowa, Iowa City.—Dr. James A. Irwin sailed, August 9, on the *Harford* for Europe.—Drs. Hobart A. Hare, Robert G. LaCount, John C. DaCosta, Judson Daland and Morris B. Miller have been promoted from lieutenant-commanders to commanders, U. S. Navy.—Dr. William C. Johnson has been appointed assistant chief resident physician, Bureau of charities.—Dr. Richard H. Harte, who organized Pennsylvania Hospital Unit No. 10, has received a communication naming him a Companion of the Order of St. Michael and St. George, conferred by Great Britain in recognition of his services during the war.

VIRGINIA

Personal.—Dr. Alexander G. Brown, Jr., has been elected a member of the staff of the department of medicine of Stuart Circle Hospital, Richmond, and Dr. Benjamin H. Gray, a member of the staff of the department of obstetrics, and both have been elected members of the board of directors.—Dr. Clifton M. Miller has been reelected a member of the Richmond School Board.

Hospital Notes.—Marshall Lodge Hospital has been incorporated at Lynchburg, Va., without capital stock, with the object of conducting a hospital and training school. The incorporators are W. E. Graves, president; W. F. Holt, trustee, and P. G. Cosley, secretary, all of Lynchburg.—The opening of the new negro hospital and the Dooley Hospital for Infectious Diseases, Richmond, is being held up on account of lack of equipment. The equipment of the negro hospital will cost \$20,000 and that of the Dooley Hospital, \$6,000. Both are to be operated under the supervision of the Memorial Hospital which belongs to the Medical College of Virginia. The negro hospital, when equipped, will accommodate 200 patients, and the Dooley Hospital, thirty-six.

WISCONSIN

Personal. Dr. Gustavus I. Hogue, Lieut.-Col., M. C., U. S. Army, Milwaukee, has returned after two years' service in France.—Dr. Joseph P. Donovan, Madison, is reported to be seriously ill with disease of the stomach.—Dr. Francis J. Broghammer, Superior, has been placed in charge of the free clinic for venereal diseases soon to be opened in Superior.—Dr. Edward G. Birge, son of President Birge of the University of Wisconsin, Madison, has been appointed state epidemiologist of Iowa, succeeding Dr. John H. Hamilton, Iowa City, resigned.

GENERAL

Gift to Red Cross.—The Abyssinian Mission, which recently arrived in the United States, brought to the national headquarters of the American Red Cross two 4500 Bank of England notes, approximately \$5,000, to be used in the work of the American Red Cross.

Nurses Cooperate with Cancer Control Society. The American Nurses' Association, National League for Nursing Education and National Organization for Public Health Nursing have adopted resolutions pledging cooperation with the American Society for the Control of Cancer in its endeavors to obtain and disseminate information regarding the prevalence, treatment and prevention of cancer.

Sioux Valley Physicians Meet.—The annual meeting of the Sioux Valley Medical Association, whose membership includes the states of South Dakota, Iowa, Nebraska and

Minnesota, was held in Sioux Falls, S. D., July 16 and 17, under the presidency of Dr. Joseph G. Parsons, Sioux Falls. Dr. Alfred E. Spaulding, Luverne, Minn., was elected president; Dr. John A. Dales, Sioux City, Iowa, secretary, and Dr. Walter R. Brock, Sheldon, Iowa, treasurer.

Methodist Hospital Activities.—According to an article in the *New York Christian Advocate*, May 29, 1919, the Methodists now have forty-seven hospitals, with a property and endowment value of \$10,000,000, at which 100,000 patients, exclusive of outpatients, are treated annually. The creation of a board of philanthropies, to have general charge of the hospitals and related institutions, will be considered in the next quadrennial conference, which will meet at Des Moines, Iowa, in 1920.

Motion Picture "Our Children."—The Children's Bureau of the Department of Labor has made its first public showing of the bureau's motion picture, entitled "Our Children." This picture shows how the citizens of Gadsden, Ala., organized for child welfare and what they did to Gadsden to make it a safe place for children to grow up in. These pictures are being shown in towns visited by the child welfare special and the events depicted are said to be typical of actual happenings which have taken place and are taking place all through the country as a result of children's year.

Bequests and Donations.—The following bequests and donations have recently been announced:

Presbyterian and St. Luke's hospitals, New York City, each \$5,000 by the will of Henry B. Macé.

St. Luke's Hospital, New York City, \$609,548.78; Staten Island, N. Y., Hospital \$40,000; St. John's Hospital, Brooklyn, and St. Luke's Hospital, San Francisco, each \$20,000, and Nassau Hospital, Mineola, N. Y., \$10,000 by the will of William H. White, Cold Spring, N. Y.

The income of the Bartlett Memorial Fund of \$100,000, to be devoted for ten years to medical work; medical mission in the Philippine Islands so long as they are United States territory, \$50,000 to be known as the Elizabeth Gale Memorial Fund by the will of Mrs. Emma Gale Harris, Chicago.

St. Luke's Hospital, Chicago, \$500 a year for ten years, by the will of Mrs. Josephine N. Smith, of Jacksonville, Ill.

The High Cost of Living.—According to a report of the National Industrial Conference Board, just issued, the cost of living for American wage earners was 71 per cent. higher in July, 1919, than at the outbreak of the world war in July, 1914. The advance is approximately 6 per cent. since March, 1919, and 12 per cent. since June, 1918. In making this estimate, the costs of food, shelter, clothing, fuel, heat, light and sundries are taken into account. In judging prices of food the board uses the average retail prices as collected for the United States Bureau of Labor statistics. The remaining figures used were obtained through questionnaires to merchants, real estate brokers, and others regularly selling the items concerned. Among food items which have made particular advances since June, 1918, were: coffee, 41 per cent.; butter, 24 per cent.; sugar, 16 per cent., and milk, 15 per cent. Sugar, pork, potatoes, flour and lard advanced more than 100 per cent. from June, 1913, to June, 1919. The average rise in rents since 1914 has been 28 per cent.; clothing, 13 per cent. in the last year and 100 per cent. in the last five years. Fuel, heat and light have advanced 57 per cent. in five years. Sundries, including tobacco, candy, ice cream, drugs, household furnishings and supplies have advanced in general a total of 63 per cent. in five years, and 5 per cent. in the last three years.

Enforcement of the Harrison Narcotic Law.—Under date of July 31, 1919, the commissioner of internal revenue issued to collectors of internal revenue a circular letter of instruction relative to the enforcement of the Harrison Narcotic Law with regard to which recent decisions of the Supreme Court of the United States have a vital bearing. While vigorous enforcement of the Narcotic Law is greatly needed, and must obtain, it is not to be enforced in such a manner as to bring unwarranted suffering. Renewed attention is called in the circular to the fact that the constitutionality of the Harrison Narcotic Law has been clearly upheld by several decisions of the Supreme Court of the United States, as already stated. It has also been held by the Supreme Court that an order for narcotics issued by a practitioner to a habitual user for the purpose of providing him with a supply sufficient to keep him comfortable and not with a view to curing him of the habit renders the practitioner guilty of an indictable offense.

The decision of the circuit court in the Thompson case affirmed the conviction of a physician who furnished narcotics to an addict, although the defense was set up that the narcotics were furnished in decreasing quantities in an attempt to cure addiction. In opposition to the physician's

defense it was shown by the testimony that the physician did not personally attend the addict or give him personal attention sufficient to prove that he was practicing in good faith. This is an important decision and indicates that the courts do not intend to allow the defense of professional treatment to hold without supporting testimony that bona fide personal supervision was given in the case. In the Oliver case the charge to the jury as delivered by U. S. Circuit Judge Woods is important. The case concerned the sale of paregoric which has increased very rapidly since the passage of the Narcotic Law. If prescribed as a medicine paregoric is exempt under Section 6 of the Act, but if prescribed for the purpose of evading the intentions and provisions of the Act by supplying addicts with a preparation with which to satisfy their addiction "then the offense was complete" and the defendant "would be guilty."

In the administration of the law many emergency cases naturally arise. As an aid in deciding such cases the following suggestions, subject to modifications through further interpretation of the law by the courts, have been submitted by the commissioner of internal revenue:

1. USE OF NARCOTICS IN THE TREATMENT OF INCURABLE DISEASE, OTHER THAN ADDICTION

With reference to persons suffering from a *proven incurable disease such as cancer, advanced tuberculosis and other diseases* well recognized as coming within this class, the reputable physician directly in charge of bona fide patients suffering from such diseases may, in the course of his professional practice, and strictly for legitimate medical purposes, prescribe narcotic drugs for the immediate needs of such patients, provided said patients are personally attended by the physician and that he regulates the dosage himself. The prescriptions in such cases should bear the endorsement of the attending physician to the effect that the drug is to be dispensed to his patient in the treatment of an incurable disease.

Such bona fide cases of incurable disease should not occasion difficulty in the proper administration of the law, and the fact that the patient suffering from such incurable disease is addicted to the use of narcotic drugs should not complicate the matter. In this class of cases, as well as in others hereinafter mentioned, caution should be exercised to avoid being imposed upon by unscrupulous persons, and too much credence should not be given to the unsupported statements of the addict himself, because the confirmed addict will go far beyond the truth in an attempt to secure an ample supply of narcotic drugs with which to satisfy his craving.

The primary responsibility obviously rests upon the physician in charge of the case. The Bureau manifestly is not charged with the duty of laying down any fixed rule as to the furnishing of drugs or the frequency of the prescriptions in any particular case involving an incurable disease. The danger of supplying persons suffering from incurable diseases with a supply of narcotics must be borne in mind, because such patients may use the narcotics wrongfully, either by taking excessive quantities or by disposing of a portion of the drugs in their possession to other addicts or persons not lawfully entitled thereto.

While the primary responsibility rests upon the physician in charge, a corresponding liability also rests upon the druggist who knowingly fills an improper prescription or order whereby an addict is supplied with narcotics merely for the purpose of satisfying his addiction.

2. AGED AND INFIRM ADDICTS

Cases will come to your attention where aged and infirm addicts suffering from *senility, or the infirmities attendant upon old age*, and who are confirmed addicts of years' standing will, in the opinion of a reputable physician in charge, require a *minimum amount of narcotics in order to sustain life*. In such cases prescriptions to meet the absolute needs of the patient may be written and filled without involving a criminal intent to violate the law. Even in these cases every reasonable precaution should be exercised to prevent the aged and infirm addict becoming the innocent means whereby unauthorized persons may engage in the illicit use and traffic in these habit-forming drugs. Prescriptions in this class of cases should bear the endorsement of a reputable physician to the effect that the patient is aged and infirm, giving age, and certifying that the drug is necessary to sustain life.

3. THE ORDINARY ADDICT

One of the principal difficulties in administering this law will arise in the case of the ordinary addict who is neither aged nor infirm nor suffering from an incurable disease. *Mere addiction alone is not recognized as an incurable disease*. It is well established that the ordinary case of addiction yields to proper treatment, and that addicts can be taken off the drug and when otherwise physically restored and strengthened in will power will remain permanently cured. The average addict does not believe this and it is symptomatic with him to have a fear and distrust of any treatment or cure. Wherever the occasion presents itself, the hope of successful treatment should be instilled in the minds of the unfortunate addicted to this terrible habit.

Addicts who have been deprived of the drug their system craves suffer frequently most terribly. While in this condition they are likely to become public charges, since they are a menace to life and property. At the present time certain municipal and state authorities are endeavoring to handle

addicts, but a project is being considered through which the U. S. Public Health Service will take over their care. Congress, however, has made no appropriation for the purpose as yet. In certain cities, namely, New York, New Orleans and Memphis, public clinics have been established for drug addicts, and the suggestion is made to the collectors of internal revenue that they should support such undertakings in their respective districts.

The Bureau of Internal Revenue makes it distinctly understood that it does not approve the so-called reductive ambulatory treatment for the reason that when the addict controls the dosage he will not be cured; then, too, through deception he may secure a supply of drugs for peddling purposes.

FOREIGN

Strike Suspends Publication of Swedish Medical Journals.

—The Swedish Medical Association announces that on account of the prevailing strike of printers the publication of their three periodicals is temporarily suspended. This includes *Hygiea* and the *Handlingar* and *Förhandlingar* published by the Association.

Memorial to Hugh Owen Thomas.—The Medical Institution of Liverpool is establishing a foundation for an oration as a memorial to the late Hugh Owen Thomas, the orthopedic surgeon. What form the memorial will take depends on the support received, either the erection of a statue or bust, together with the foundation of an oration in that branch of surgery which Hugh Owen Thomas did so much to create. Primarily, the object is to create a Hugh Owen Thomas Memorial Lecture. Subscriptions to the fund may be sent to Dr. C. Thurstan Holland, Medical Institution of Liverpool, England.

LATIN AMERICA

New Laboratory at Valparaiso.—A new hygienic laboratory provided with the most modern equipment has been recently inaugurated at Valparaiso, Chile, in connection with the hospital of San Juan de Dios. The laboratory comprises sections devoted among others to bacteriology, chemistry and serum manufacture.

Work of Child Congress in Montevideo.—Among the resolutions adopted at the *Segundo Congreso Americano del Niño* held at Montevideo in May, 1919, appear the following: recommending a prophylactic campaign on behalf of tuberculous children; recommending the compulsory teaching in schools of the prophylaxis of tuberculosis, syphilis, alcoholism, echinococcus cysts and malaria; establishment of systems of school medical inspection with special reference to the prevention of tuberculosis; establishment of special bureaus to prevent infant mortality; a greater uniformity in the collection of statistics on infant mortality; extending the protective measures so that they will begin with the pre-conceptional period and continue until the child reaches adolescence; the consolidation in one single office of all work relating to the protection of infants; regulating the work of pregnant women; extending as far as possible to the homes themselves the protection of children; offering prizes to mothers who nurse their infants; having at all infant stations (whenever practicable) mother's milk available for distribution; adoption of legislation requiring physicians to write their prescriptions on sheets having on the back a series of hygienic precepts, these prescriptions to be kept by the patient and not by the druggist; instituting a prenatal system of prophylaxis against ophthalmia neonatorum without neglecting the Crede method of treatment; making compulsory the reporting of ophthalmia neonatorum; intensification of the antitubercular propaganda; teaching of hygiene in primary schools, especially as related to children; organization of a system of dental dispensaries in schools and making compulsory the examination of all children's teeth.

In the section of medicine the resolutions adopted dealt especially with the desirability of having at the third Congress a number of papers on the gastro-intestinal disturbances of infants, the importance of maternal nursing and the necessity of securing sanitary dwellings for workmen.

Another resolution adopted by the Congress provided for the creation of an American international office for child welfare work in general, to be located at Montevideo and to represent all the countries that may desire to join it. The Congress was presided over by Dr. Luis Morquio, the professor at the University of Montevideo, and well known pediatricist, and was well attended, especially from Uruguay and neighboring countries.

PARIS LETTER

PARIS, July 17, 1919.

Treatment of Acute Appendicitis

At a recent meeting of the Academy of Medicine, Dr. Témoigné of Bourges contributed a communication on the treatment of acute appendicitis which remains one of the most interesting subjects of surgery by reason of the extreme frequency of appendicitis, its increasing severity during the influenza epidemic, and the division of surgeons, with regard to operative procedure, into abstentionists and interventionists. The most generally accepted doctrine is that one should not operate in case the crisis has lasted more than thirty-six hours, but that, this period once past, one should pursue a waiting policy until defervescence is accomplished. Témoigné does not share this opinion. He does not think a question of hours should influence the surgeon when dealing with an affection so variable in its course, in its symptoms and in its severity. In the period between 1911 and 1919 he has operated in all the cases of appendicitis he has encountered, no matter how serious they were, and it has been rather the exception for the operation to be performed during the first forty-eight hours. He has performed 1,175 operations, and his testimony is to the effect that the percentage of cures varies not by reason of the number of hours that have elapsed since the beginning of the crisis but depends on the character of the lesions and the disturbances caused by the infection. The percentage of recoveries, he states, is 100 per cent. when the lesions are limited to the appendix. The mortality, on the contrary, varies between 5 and 20 per cent., in case peritonitis has resulted as a consequence of the perforation, and is in direct proportion to the stage of evolution reached. The indications are then for as early an operation as possible, but one should not decline to operate because the beginning of the crisis dates back more than thirty-six hours. Témoigné emphasizes the importance of certain details of technic and certain symptoms. In any event, from a statistical standpoint his records are complete, since he has operated in all the cases that he has encountered and in all the phases of their evolution. His records permit an instructive comparison of resolution and the advantages of surgical intervention with the results and the dangers of the waiting policy.

Dr. P. Reynier, hospital surgeon and professor on the faculty of the Paris School of Medicine, remarked that in many forms of appendicitis the indications for operation depended on the cases. Témoigné stated that at the beginning of a case of appendicitis one could not know what its course would be. When the symptoms are moderate in the beginning it does not follow that the case will develop favorably. For patients living out in the country the waiting policy is especially harmful and favors the development of a generalized peritonitis. It is a question of symptoms and not of hours which should guide the surgeon in acute appendicitis as well as in purulent salpingitis.

Annual Neurologic Reunions

The Société de neurologie de Paris, thinking that it would be eminently worth while to secure an exchange of views between the neurologists of France and the neurologists of all the allied and neutral countries, has just formulated a plan for the holding of annual neurologic reunions to which will be invited all the members of the national society, its foreign correspondents, and neurologists and psychiatrists from other countries.

These annual reunions will be held in Paris in the month of June or July. A two-day meeting, with two sessions each day, is planned. A question that awakens both scientific and practical interest will be chosen as a subject of study and will be presented in a brief paper by some one designated in advance to have authority to open the discussion. The discussions and the communications will bear solely on the subject of general neurology. The first of these reunions will be held in 1920, and the subject chosen is: "Les formes cliniques et thérapeutiques de la syphilis nerveuse" ("The Clinical Forms and the Method of Treatment in Neurosyphilis").

Franco-American Medical Relations

At the instigation of Dr. Delbely, an organization has been formed in Paris which has for its purpose the establishment of constant relations between American and French medical men. At an informal gathering at which some thirty surgeons and physicians of Paris were present, a provisional committee was formed and various subcommittees were appointed. One subcommittee purposes to study the necessary means to bring about an exchange of articles in the press of the two countries. Another subcommittee will occupy

itself with the organization of postgraduate courses of instruction of such a character that American physicians spending a short time in France may take advantage of it without losing a moment's time. A third subcommittee is charged with the duty of collecting such information and providing such arrangements as will make their stay in France as pleasant as possible.

LONDON LETTER

LONDON, July 17, 1919.

Tetanus in the War

Analyses of the cases of tetanus treated in the home military hospitals, made by a committee of investigation appointed by the War Office with Major-Gen. Sir David Bruce as chairman, have been given in previous letters. A tenth analysis for the period from April to September, 1918, and an eleventh for September, 1918, to March, 1919, have just been issued. The total number of cases in the whole series was 1,420, and the average incubation period, 39.5 days. In the tenth analysis there were eighty-seven cases of general tetanus and thirteen cases of local tetanus; the rate of mortality in the former was 29.9 per cent.; among the latter there were no deaths. In the eleventh analysis there were eighty-six cases of general, and fourteen of local tetanus; the rate of mortality in the former was 30.2, and among the latter there were again no deaths. On the recommendation of the adviser in pathology to the army in France (Sir William Leishman), the primary prophylactic dose of antitetanic serum was changed from 500 to 1,500 units. This increase, which was instituted in November, 1918, should show its good effect, if any, on the incidence of the disease among all wounded rather than in the rate of mortality among cases of declared tetanus. The prophylactic value of antitetanic serum is now established, but clinical and experimental evidence goes to show that within about ten days the immunity produced begins to decline. Accordingly, the Tetanus Committee advised that four prophylactic injections should be given to every wounded soldier at intervals of seven days. The army medical authorities decided that all wounded men, including patients with trench foot and frost bite, should receive at least four subcutaneous injections—the first at the time of the wound. Instructions were also issued that accidental wounds received at home—especially those contaminated with dirt—should be treated in the same way. These multiple prophylactic inoculations have been in vogue more or less since the beginning of 1917, but the number of wounded men receiving four inoculations has varied much according to the energy of the local authority. The results are not yet available, but the known figures suggest strongly that the death rate among those who contract tetanus tends to fall as the number of injections increases from one to five. Hence the Tetanus Committee recommends that until our knowledge of the immunizing process in tetanus is more advanced, these multiple injections should be continued.

Early in 1918, Major Carroll Bull, C. S. M. C., demonstrated his method for the production of the toxin of gas gangrene (*B. welchii*). Dr. R. A. O'Brien, of the Tetanus Committee, at once began to prepare a double serum containing the antibodies of tetanus and gas gangrene, and the committee recommended the use of this double serum as soon as possible so that its value might be tested. By the middle of July, 100,000 doses were sent to France. At a War Office conference held in November, 1918, it was decided to add the antitoxins of *Vibrio septique* and *B. oedematis* to the double serum. In the last two analyses of cases treated in home hospitals, only two cases are noted in which the injection of double serum was given, and both the patients recovered. It appears that this "tetanus plus gas gangrene serum" in the strength used was not a marked success in the prevention of gas gangrene, though there is no evidence that the addition of antitoxins of other anaerobes had any effect, good or bad, on the tetanus antitoxin.

With regard to treatment of tetanus, the Tetanus Committee holds that "in acute general tetanus the best method lies in the earliest possible administration of a large dose of antitoxin by the intrathecal route, repeated on the following day, combined with and followed on succeeding days by subcutaneous and intramuscular injections." In acute general tetanus the best results were obtained from very large doses. Analyses of the last two series of 100 cases treated are neither for nor against the intrathecal route.

Sir Douglas Haig's Criticisms of Pensions for the Disabled

In giving evidence before the Select Committee on Pensions at the House of Commons, Sir Douglas Haig severely

criticized the methods followed. He said that in the late summer of 1918 he was appalled by the evidence received as to the methods of the state to provide for the disabled. Not only were the cases dealt with by the Disabled Officers' Fund brought under his notice, but he daily received letters from all parts of the country with the same piteous appeal. Since then matters had been in some degree improved, but not so far as the officers were concerned. He held strongly that it was the duty of the state to provide for those who had suffered in the war, but he was prepared to admit that there might be small gaps which might be filled by voluntary effort. The strain thrown on charitable institutions was sufficient condemnation of government methods and proof of the inadequacy of state pensions. In the first place, he held it was necessary to have a single authority to coordinate and advise the three ministries—war, pensions, and labor—that were affected. There was no chain of responsibility. The War Office should not discharge until the Pensions Ministry could take responsibility, and the Pensions Ministry should hold until the Ministry of Labor could make provision. Of medical boards, Sir Douglas said: "In some cases the members of the board are ignorant of the actual disease suffered. In others they are lacking in all sympathy and generosity. There is no uniformity in their decisions, and some treat every individual who appears before them as a malingeringer. I strongly advise the appointment of a selected combatant officer to act as assessor so as to produce some confidence in the decision. Again, in some cases the disability is reassessed at the Ministry of Pensions to the individual's disadvantage. That this should be done without the individual being seen or heard is contrary to all ideas of British justice." He advocates a more generous provision for the wives and children of officers and men, and also for the education of their children. The total disability rates for both officers and men were inadequate. The weekly allowance should be increased to at least \$10. He urges a more generous and sympathetic treatment to all who suffered from gas poisoning, shell shock and neurasthenia. Their suitable treatment was no easy matter. Employers were shy of giving them appointments. Immediate reform in the method of treatment was called for. After paying tribute to the courtesy and sympathetic attitude of the present minister of pensions and to the excellent work of the present officers, Sir Douglas appealed for: (1) a greater generosity on the part of the state; (2) a single authority to coordinate the work of ministers, and (3) an improvement in the machinery, which was working laboriously but too slowly and in many cases unsympathetically.

The Ministry of Health

A three-day conference, arranged by the Royal Institute of Public Health, has been held at the Guildhall to discuss the powers and policy of the newly constituted Ministry of Health. The conference was attended by representatives of the local health authorities throughout the country and by a number of well known physicians interested in public health. Sir Kingsley Wood, M.P., said that the Local Government Board was about to disappear, and that a new era would begin in the health administration of the country. In the past, to a large extent, prevention had been lost sight of. Health problems had been dealt with by jerks and fits and starts, and a large part of the health organizations set up had followed the outbreak of some epidemic or pestilence. There had been utterly inadequate provision for research. A beggarly sum of \$300,000 a year had been granted by the government. Under the new health ministry they hoped to found an important medical research department with branches in different towns. Our present system, to a large extent, had taken a parochial and not a national view of health affairs. There were no fewer than twenty-one government departments or sections dealing with health affairs, and the whole of them were largely interested in matters which had nothing to do with health at all. We had now got one minister solely responsible to Parliament and to the country. The war had brought forward the question of stamping out venereal disease, and the Ministry of Health started on its career today facing that tremendous problem. Motherhood and child welfare and the better treatment of tuberculosis also demanded provision.

The following resolutions were carried, and it was decided to forward them to the Minister of Health: 1. Sanitary inspectors, health visitors, and similar classes of public health officials should be adequately trained, and the present system of examinations should be coordinated so as to secure one qualifying examination for the whole country. 2. The conference views with satisfaction the contemplated creation of advisory councils in connection with the work of the

Ministry of Health, and urges that the services of those who have had long and practical experience in administrative and executive public health should be secured on those councils. 3. In view of the large national demands which will be made on the Ministry of Health as an organizing and controlling center, it should not be burdened with functions of detail which may deprive the local authorities of the sense of responsibility and a sense of initiative. 4. In view of the invaluable services rendered by women who are serving as elected or co-opted members on local authorities, or as officers of such authorities, women should be included in large numbers on all advisory bodies, and greater facilities should be provided for the training of expert women workers in the homes of the people. 5. All questions comprised within the scope of port and maritime sanitation should receive the earnest attention of the Ministry of Health, and, in order to insure greater cooperation and confidence between British and foreign port authorities, the widening and readjustment of the agreements reached at the International Sanitary Convention are necessary. 6. Greater use should be made of the services of the British consuls in foreign ports in obtaining and transmitting information relative to the sanitary conditions of the ports. The smaller authorities should be joined together with the object of securing the whole-time services of health officers.

British Versus German Hygienic Methods in Tropical Medicine

The war has revealed the exaggerated estimate of German methods generally held and has shown that in spite of "thoroughness," they are by no means necessarily superior to those of other countries. An interesting illustration how they have been surpassed by British methods is furnished in an account by a high official from Dar-es-Salaam given to the *Morning Post*. The Germans on the East Coast of Africa, of course, recognized the connection between malaria and *Anopheles maculipennis*. But their way of combating the malarial mosquito was very unscientific, though typically German in other respects. They enclosed only the important buildings with fine-mesh wire-netting screens to keep out the mosquitoes. But that made an intolerable condition by preventing the circulation of the air and still left human beings open to mosquito bite if they lived outside the compounds or when they left them. The British military authorities, on taking possession, went to work much more soundly. They attacked the malaria at its source by carrying on a war of extermination against the mosquito. It was practically the same method which the Americans had followed with such success in Panama, and a British soldier who had seen service against the mosquito in Central America was of great value in this campaign. Swampy places were drained off, and ditches were deepened and graded to guard against stagnant water. Pools were oiled and fish introduced to eat the larvae of the mosquito. When ponds could not be oiled, larva-eating fish were introduced. One experiment of this kind failed at first from an unforeseen cause. The fish were introduced to the pond. Within a few days aquatic birds preyed on them. Another experiment was then made. Some broad-leaved aquatic plants were first introduced, and then the fish. The leaves of the plants protected the fish from the birds, and the mosquitoes were overcome. The anopheline mosquito, and with it malarial fever, has been practically banished from Dar-es-Salaam. The campaign, too, is being extended from there to other parts of German East Africa, the natives being trained in mosquito extermination.

British and American Surgeons in France

The *Times* has published a special supplement on America in the war. As the medical work was not noticed, Sir Anthony A. Bowlby (lately consulting surgeon, British armies in France), has in a letter drawn attention to the closeness of the sympathy which existed, both before and during the war, between the medical professions of the United States and of Great Britain. An American unit from Harvard University, completely staffed one of our general hospitals in France as early as 1915, and in 1917 six more British hospitals in France were staffed by the United States. In 1917 the British Army in France had from 100 to 200 American surgeons working on our front with regiments, field ambulances and casualty clearing stations, and not a few of them were killed or wounded. The services they rendered at a time when we were very short of surgeons should never be forgotten, and it would be impossible to overestimate the cordial good fellowship and mutual regard and esteem which prevailed everywhere.

Marriages

JOHN EDWARD WATTENBERG, Lieut., M. C., U. S. Army, Berger, Mo., on duty at Fort Des Moines, Iowa, to Miss Ione Crenshaw of San Diego, Calif., at Fort Des Moines, July 17.

ROBERT BOYD PRATT, Lieut.-Col., M. C., U. S. Army, Bellefontaine, Ohio, to Mlle. Adrienne Pairoteau of Vendee, France, recently.

RICHARD OPRIN, ADAMS, Capt., M. C., U. S. Army, Columbus, Ohio, to Miss Newman of Hampstead, London, England, June 25.

WILLIAM GARRETSON CARHART, Major, M. C., U. S. Army, Minneapolis, to Miss Floyd Foreman, in Chicago, July 17.

HENRY FRANKLIN SCHANTZ, Reading, Pa., to Miss Irene G. Clark of Niagara Falls, N. Y., at Reading, July 23.

STUART McGUIRE, Richmond, Va., to Miss Ruth Isabelle Robertson of Walker, Ont., August 12.

JAMES GILMER STONE, West Grove, Iowa, to Miss Frances Heaton of Des Moines, Iowa, July 29.

FRANKLIN HARRISON HOPPER to Miss Demaris Marie Berkey, both of Cleveland, August 7.

WILLIAM FREDERICK MAYER to Leone Elizabeth Rabb, both of Johnstown, Pa., June 25.

FRANK WHITE McCORMIE to Miss Mamie Woodfin, both of Uniontown, Ala., August 6.

Deaths

Charles Calvin Moyer * Lincoln, Neb.; Baltimore University School of Medicine, 1893; aged 52; for six years a pharmacist at Hartleton, Pa.; but for the last twenty years a practitioner of Lincoln; secretary of the faculty and professor of obstetrics in the Nebraska College of Medicine until the discontinuance of the institution in 1908; gynecologist and president of the staff of St. Elizabeth's Hospital, Lincoln, for several years; died at his home, July 30, from carcinoma.

Hanson Thomas Asbury Lemon * Washington, D. C.; George Washington University, Washington, D. C., 1890; aged 50; surgeon to the Southern Railway system, and president of the Association of Surgeons of the Southern Railway; local surgeon of the Pennsylvania and Chesapeake and Ohio systems; president of the Washington Society for Mental and Nervous Diseases; died at his home, July 21, from encephalitis.

Zelotas Clifford Wolfe, Corydon, Ind.; Kentucky School of Medicine, Louisville, 1881; aged 63; a member of the Indiana State Medical Association; for eighteen years head medical examiner for the Modern Woodmen of America and Independent Order of Odd Fellows; who was operated on in St. Anthony's Hospital, Louisville, Ky., July 23, for abscess of the gallbladder; died in that institution, July 26.

Otis Johnston, Quincy, Ill.; Chaddock School of Medicine, Quincy, Ill., 1887; aged 52; a member of the Illinois State Medical Society and for several terms president of the Adams County (Ill.) Medical Society; local surgeon for the Burlington and Quincy, Omaha and Kansas City railroads; surgeon in charge of St. Mary's Hospital, Quincy; died at his home, July 21, from heart disease.

Oliver Perry Brittin * Capt., M. C., U. S. Army, Athens, Ill.; Barnes Medical College, St. Louis, 1908; aged 35; secretary of the Menard County (Ill.) Medical Society in 1914; who recently returned from overseas; while driving over a grade crossing near Springfield, Ill., in his automobile, July 2, was struck by a train and instantly killed.

Gaston A. Hebert * Hot Springs, Ark.; Tulane University, New Orleans, 1895; aged 46; lecturer on physiology and hygiene in the St. Joseph's Hospital Training School for Nurses, and chief of the clinic of dermatology and syphilology at St. Joseph's Infirmary, Hot Springs; died in that institution, July 17.

Charles Long, Saleville, Pa.; Albany (N. Y.) Medical College, 1897; Bellevue Hospital Medical College, 1870; aged 77; a member of the Medical Society of the State of Pennsylvania; president of the Altoona (Pa.) Board of Health in 1897; died in the Altoona Hospital, July 8.

Daniel James Kelly, Washington, D. C.; Georgetown University, Washington, D. C., 1875; aged 75; assistant chief examiner in the patent office, Washington; for nearly forty years professor of physiology, chemistry and toxicology in his alma mater; died in Providence Hospital, Washington, July 26.

Charles Frederick Myers, Albany, N. Y.; Albany (N. Y.) Medical College, 1910; aged 35; a member of the Medical Society of the State of New York; attending physician to the Central Federal Tuberculosis Clinic; was instantly killed in an automobile accident in Albany, July 30.

Luke F. Bonner, Barwell, S. C.; Medical College of the State of South Carolina, 1891; aged 51; a member of the South Carolina Medical Association; died at his home, July 25, from septicemia, three days after a surgical operation performed in a hospital in Augusta.

Edgar Mortimer Day, Pittsburgh; Johns Hopkins University, Baltimore, 1918; aged 28; who served overseas as first lieutenant, Medical Corps, with Base Hospital No. 18; was drowned at the family summer home at Point au Baril, Georgian Bay, Ont., July 23.

Henry Zimmermann * Lieut., M. C., U. S. Army, Springfield, Mass.; University of Maryland, Baltimore, 1912; aged 30; recently discharged from the Army; was shot and killed in Springfield, August 7, by a woman whom he is said to have refused to marry.

Luke Teskey, Toronto; Trinity Medical College, Toronto, 1877; aged 70; a member of the faculty of the University of Toronto, and on his retirement made emeritus professor; died in the Toronto Hospital, May 1, from carcinoma of the pylorus.

Jay D. Whelpley, Howard City, Mich.; Grand Rapids (Mich.) Medical College, 1901; aged 49; a member of the Michigan State Medical Society; died at his home, May 26, from cholecystitis and pancreatitis following influenza.

Davis Herren * Lieut., M. C., U. S. N. R. F., Crownpoint, N. M.; Memphis (Tenn.) Hospital Medical College, 1912; aged 31; formerly in the United States Indian Service; died in Colorado Springs, Colo., July 25, from tuberculosis.

Carter H. Smith, Lebanon, Ind.; Rush Medical College, 1873; aged 84; who on completion of a half century of practice in 1911, was given a banquet by the Boone County Medical Society; died at his home in Lebanon, July 25.

Alexander George Crockett, Max Meadows, Va.; Vanderbilt University, Nashville, Tenn., 1885; aged 57; a member of the Medical Society of Virginia; senator from his district for four years; died at his home, July 27.

William Patrick Sweeney * Capt., M. C., U. S. Army, Saratoga Springs, N. Y.; Albany (N. Y.) Medical College, 1915; aged 26; was instantly killed in an automobile accident in Albany, N. Y., July 30.

George K. Olin, Brownville, N. Y.; Long Island College Hospital, Brooklyn, 1918; an intern in the Seaside Hospital, Coney Island, N. Y.; was drowned while bathing near the hospital, July 17.

Charles D. McCarthy * Geneva, N. Y.; University of Buffalo, N. Y., 1888; aged 58; health officer of Ontario County, and surgeon to the Geneva Hospital; died, July 8, from general endarteritis.

Effie A. Current, Danville, Ill.; Medical College of Indiana, Indianapolis, 1901; aged 44; at one time coroner of Kearney County, Neb.; died at her home, June 11, from tuberculosis of the lungs.

Seth James Cradup, Julian, Neb.; Baltimore Medical College, 1890; aged 61; who was operated on for carcinoma of the stomach, July 18; died in a hospital in Richmond, Va., July 20.

Bearaugard W. Flinn, Little Rock, Ark.; Memphis (Tenn.) Hospital Medical College, 1881; aged 57; a member of the Arkansas Medical Society; died at his home, July 24.

Henry Dousin Leitch, Vancouver, B. C.; Trinity Medical College, Toronto, 1884; aged 60; died in the Vancouver General Hospital, April 21, from pyonephrosis.

Frank Albert Towsley * Midland, Mich.; University of Michigan, Ann Arbor, 1880; aged 61; died at the Battle Creek Sanitarium, July 23, from nephritis.

William Deadrick Nelson, Jr., Canton, Ill.; Rush Medical College, 1884; aged 62; a member of the Illinois State Medical Society; died at his home, July 28.

Edward Richard Trippe, Easton, Md.; University of Maryland, Baltimore, 1862; aged 79; died at his home, July 1.

* Indicates "Fellow" of the American Medical Association.

The Propaganda for Reform

IN THIS DEPARTMENT APPEAR REPORTS OF THE COUNCIL ON PHARMACY AND CHEMISTRY AND OF THE ASSOCIATION LABORATORY, TOGETHER WITH OTHER MATTER TENDING TO AID INTELLIGENT PRESCRIBING AND TO OPPOSE MEDICAL FRAUD ON THE PUBLIC AND ON THE PROFESSION

HORMOTONE AND HORMOTONE WITHOUT POST-PITUITARY

Report of the Council on Pharmacy and Chemistry

"Hormotone," of the G. W. Carnrick Company, is advertised as "A pluriglandular tonic for asthenic conditions." "Hormotone Without Post-Pituitary" is recommended for use "in neurasthenic conditions associated with high blood pressure." These preparations are sold in the form of tablets for oral administration. The Council declares these preparations inadmissible to New and Nonofficial Remedies because: (1) Their composition is semisecret (Rule 1); (2) the therapeutic claims are unwarranted (Rule 6); (3) they are sold under names not descriptive of their composition but suggestive of indiscriminate use as "tonics" (Rule 8); (4) in the light of our present knowledge the routine administration of polyglandular mixtures is irrational (Rule 10). In explanation of this action, the Council authorized publication of the report which appears below.

W. A. PUCKNER, Secretary.

Each tablet of "Hormotone" (G. W. Carnrick Co., New York City) is said to contain $\frac{1}{10}$ grain of desiccated thyroid and $\frac{1}{20}$ grain of entire pituitary, together with the hormones of the ovary and testes—the amounts and the form in which the latter are supposed to be present are not given. From this it will be seen that the only definite information given to the medical profession regarding the composition of Hormotone is that it is a weak thyroid and a still weaker pituitary preparation.

What results can be anticipated from one or two tablets three times daily (the recommended dose of Hormotone) each containing $\frac{1}{10}$ grain of thyroid and $\frac{1}{20}$ grain entire pituitary? Such doses of thyroid may, of course, have a beneficial action in a limited number of cases of myxedema and cretinism. An extract of the posterior lobe of the pituitary (Liquor Hypophysii, U. S. P., for example) will, when injected subcutaneously or intramuscularly, have a pronounced effect on the parturient uterus; its action on certain other forms of smooth muscle will be much less certain. But the oral administration (for which Hormotone is recommended) of the posterior lobe of the pituitary has not been shown to have any such effect. The use of the anterior lobe in doses of 1 to 4 grains (doses very many times larger than those recommended for the entire gland in Hormotone) is in the experimental stage and its only probable value seems to be in those cases of known gland deficiency.

As to the other alleged ingredients of Hormotone—hormones of the ovary and testes, amounts not stated: all physicians know the uncertainties attending the use of ovarian preparations and the serious question as to whether testicular extracts have any therapeutic value. Whatever may be the physician's views as to the probable therapeutic value of these organs, the first thing he desires to know is how much of the substance he is giving and from what part of the gland it is obtained.

So much for the facts; yet the physician is asked to jump from this region of solid fact into a sea of hypothesis; to believe that small amounts of the well-known drugs thyroid and pituitary, plus an unknown amount of unknown hormones of the testes and ovary are of great value in conditions that in themselves are often purely hypothetical. He is asked to believe that this combination has virtues in such conditions as "hypo-function of the adrenal system," neurasthenia, the "fatigue syndrome," amenorrhea, dysmenorrhea, "natural and artificial menopause," sexual neuroses, cold extremities, cardiac asthma, low blood pressure, infantilism, sterility, melancholic conditions, obesity, anorexia, anemia, slow metabolism,

constipation, psychasthenia, lowered virility and the sexual neuroses of the unmarried, hysteria following functional exhaustion of the nerve centers, frigidity, etc., etc., especially if he guesses that the trouble is due to a "pluriglandular disturbance," "glandular hypofunction," an "adreno-pituitary deficiency," suboxidation, etc.

The physician is invited to use Hormotone because, among other reasons, each alleged constituent is said to be "in physiologic sympathy and therapeutic harmony with the others," and further, because:

"Pluriglandular therapy has the endorsement of high authorities, is both logical and effective and Hormotone is a splendid example of it. It will be seen at its best where the patient lacks snap and vim and vigor. Asthenic conditions necessarily indicate hypofunction of the adrenal system . . . " etc.

"The use of gland extracts in the treatment of aplasia of the pluriglandular system has become an established therapeutic measure of miraculous potency (Bavard Holmes: The Internal Secretory Glands, *Lancet-Clinic*, Sept. 19, 1941.)"

The G. W. Carnrick Company also advertises a "Hormotone Without Post-Pituitary," each tablet of which is said to contain $\frac{1}{10}$ grain desiccated thyroid, and to "present" "hormone bearing extracts of thyroid, anterior pituitary, ovary, and testes." This product is just as irrational as "Hormotone."

Correspondence

ILLINOIS' COMMENDABLE CONSOLIDATION OF MEDICAL CHARITIES WITH MEDICAL EDUCATION*

To the Editor:—Illinois has discovered that its legislature desires to do the right thing but depends on the experts of the executive departments to give it the information on which to act. It is obvious that the legislature cannot know, in advance, the details of all needs which lead to requests for legislative action. The consolidation of 125 commissions into nine departments, each in charge of a single director gave Illinois its opportunity to do things right. The results have been that laws were enforced, routine work was accomplished promptly and well, and, in spite of the war time, the total of appropriations was not exceeded, and yet the state found itself with a full treasury. The legislature, therefore, has confidence in the executive officers. It has not only asked for their advice but also acted on it and has granted all reasonable requests.

To the writer was given the administration of all of the hospitals, charitable and penal institutions of the state; he was also given certain legal duties and instructions. The department was expected to conduct research into the causes and treatment of insanity, feeble-mindedness, delinquency, dependency and crime; to train physicians, nurses and others for the special work of the department and, in general, to do whatever was necessary to perfect its service to the public. Those connected with the department could not conduct research as a matter of routine. They were not educators but professional administrators. Another creature of the state, however, the University of Illinois, was organized to do, through its medical school, the very things the department was not organized to do. A perpetual cooperative agreement has been entered into with the university, therefore, whereby the medical school will have in charge the professional work and teaching and the department of public welfare will administer the entire group of institutions, including the medical school. This arrangement provided for future development and was for the public good. The legislature promptly approved the agreement and made an initial appropriation of \$1,500,000 for the land needed and to begin the construction of a psychiatric institute, a surgical institute for children, a new eye and ear infirmary and a clinical hospital. By approving the agreement they also committed themselves to a plan requiring several millions of dollars in the future. The director of public welfare will control all building operations for both parties, and an endeavor will be made

* See editorial, p. 538.

to produce buildings which will be educational in character rather than of the institutional type. The buildings will include a clinical laboratory, a reconstruction hospital, a contagious disease hospital, a medical college and others to be added as needed.

As the department of public welfare can furnish clinical material of almost any kind and in any quantity, the result should be a state university medical school with unrivaled facilities for teaching, research and training of professional talent. The department of public welfare will benefit because it will have met its obligations and will be enabled to secure an abundance of trained specialists for its various hospitals and other institutions.

The State Surgical Institute for Children and the three other buildings provided for will be erected on the deserted Cubs' Park baseball field, Lincoln and Polk streets, Chicago, which is being purchased by the state for the sum of \$400,000. The Eye and Ear Infirmary, the largest of the group, will replace the old Eye and Ear Hospital at Clinton and Adams streets. But the hospital we are most proud of is the State Surgical Institute for Children and we plan to make it excel anything of its kind in the country. The Clinical Hospital for Children will contain every modern feature used in medical schools. The Psychopathic Hospital will devote its time to research work with the feeble-minded, studying exhaustively plans for training morons and borderline cases in useful occupations. The medical personnel at the new group will be chosen from physicians now attached to the state medical school and students graduating from the state school will be given preference for appointment as interns. Construction work on the buildings will begin in the spring.

CHARLES H. THORNTON, Springfield, Ill.

Director of Public Welfare, State of Illinois.

NEW METHOD FOR OPENING HYPO- DERMIC NEEDLES

To the Editor.—To one who is accustomed to using hypodermic needles frequently, as in the administration of vaccines and other medicinal preparations, the value of some method by which the lumen of the needles can be kept free of rust and other materials in the shortest possible time is a distinct advantage over the method of boiling in a solution of sodium carbonate, as recommended in *THE JOURNAL*, and the use of the copper wire, etc. The use of a small instrument known as the pivot broach, used by jewelers to drill very fine holes in watch repairing, permits a needle to be opened very quickly. This instrument is a three-cornered piece of tempered steel with a round handle at one end, the cutting edges being the three corners which act as a drill. It is the size of the lumen of the needle, and the same length as the average hypodermic needle. If the broach is introduced at either end with a semicircular motion, as if drilling, the needle can be entirely freed of rust or other materials. Care, of course, must be exercised in handling the broach, as it is likely to snap off if it is forced too hard in the beginning. When the needles are opened by this method, I have found them very satisfactory, and they last almost indefinitely. The broaches can be obtained from any jeweler's supply house at a very moderate cost.

MILTON H. PROSPER, M.D., Washington, D. C.

DIFFICULTY OF OBTAINING BRANDY AT DRUG STORES

To the Editor.—It seems to me that this war-time prohibition measure is a great deal too drastic as regards the medical profession and drug stores. As the measure now stands, it is almost impossible to prescribe brandy in any amount, either alone or in mixture, and have it filled at the drug stores. Practically all the drug stores here cannot afford to pay for the license for liquor, in the small amounts in which it is ordered by physicians. At present, with the large number of infant diarrhea cases in which brandy is needed as a stimulant, brandy is almost impossible to obtain

I have had quite a number of cases in which brandy was imperative, but the patient made a canvass of all the drug stores, and could not obtain any. Something should be done by the medical profession whereby prescriptions for brandy in amounts of 1 or 2 drams in medicinal mixtures could be easily and readily filled.

LIONEL L. ALBERT, M.D., Central Falls, R. I.

CALCIUM CHLORID IN INTESTINAL TUBERCULOSIS

To the Editor.—I have read with interest Dr. Maurice Fishberg's article on this subject in *THE JOURNAL*, June 28. The intravenous administration of calcium chlorid solutions as an aid in the treatment of pulmonary and glandular tuberculosis has been continuous in my practice for the past five and one-half years. I published my first report on this work in the *Indianapolis Medical Journal*, January, 1915. Since that time have used this method as an adjunct in the treatment of both pulmonary and glandular forms of tuberculosis. I am convinced that the intravenous use of calcium chlorid solutions is a distinct aid in the treatment of these forms of tuberculosis.

THOMAS J. BEASLEY, M.D., Indianapolis.

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

OPPORTUNITIES FOR MEDICAL PRACTICE IN MEXICO

To the Editor.—Please give me information regarding the opportunities for physicians and surgeons in Mexico.

J. R. E., M.D., Baltimore.

ANSWER.—At present, opportunities for American physicians and surgeons in Mexico are rather limited. In Mexico City there are already a number of American physicians who, it is reported, are more than sufficient to serve the decreased American colony. In smaller towns there may be a better opportunity, but conditions are at this moment too uncertain to make it worth while to take the chance. The American consuls would, of course, have definite information in regard to conditions in any specific state or town. A physician with exceptional ability could, of course, make room for himself practically anywhere. The practice of medicine is entirely "free" in all Mexico, with the exceptions of the states of Puebla and Jalisco, where only those having officially recognized degrees are allowed to practice.

INDUSTRIAL MEDICINE IN SOUTH AMERICA

To the Editor.—I am desirous of learning something about the opportunities in industrial medical work in Central or South America. Can you furnish me any of this wanted information through your new connections in reading the Spanish edition of *THE JOURNAL*, or can you advise me as to whom to correspond with on this subject?

W. A. J., M.D., Chicago.

ANSWER.—The opportunities for an American physician who wishes to engage in industrial medical work in Central or South America would seem to be limited to those American companies which are in business there. Among these may be mentioned the United Fruit Company, the new branches opened by meat packers in Argentina and Uruguay, and more recent ramifications of the steel industry in Peru, especially the Schwab interests. It would seem very desirable and practically necessary that any American physician going to any Spanish-speaking country should know the language. In *THE JOURNAL*, August 2, an American corporation advertises for a physician for duty in Peru. Names and addresses of American firms with business interests in Central and South America can be obtained from the United States Chamber of Commerce or the United States Bureau of Foreign and Domestic Commerce, Washington, D. C.

COMING EXAMINATIONS

ALASKA: Juneau, Sept. 2. Sec., Dr. L. P. Dawes, Juneau, Alaska.
HAWAII: Honolulu, Sept. 8-10. Sec., Dr. J. R. Judd, Honolulu, Hawaii.

ILLINOIS: Chicago, Sept. 22-25. Sec., Mr. Francis W. Shepley, Junior, Capital Bldg., Springfield.

IOWA: Des Moines, Sept. 16-18. Sec., Dr. Guilford H. Sumner.

MASSACHUSETTS: Boston, Sept. 9-11. Sec., Dr. Walter P. Bowles, State House, Boston, Mass.

NEW HAMPSHIRE: Concord, Sept. 11-12. Sec., Dr. Chas. Duncan, Concord, New Hampshire.

NEW YORK: Albany, Buffalo, New York and Syracuse, Sept. 16-19. Mr. Herbert J. Hamilton, Assistant, Professional Examinations, Albany.

RHODE ISLAND: Providence, Oct. 2-3. Sec., Dr. B. C. Richards, State House, Providence.

NEW YORK ASSOCIATION FOR MEDICAL EDUCATION

The proposal of a small group of physicians, surgeons and medical teachers of New York to establish a central clearing house for medical education has so favorably impressed their colleagues that what has been for years past a dream and a hope has now become an accomplished fact. The medical profession has developed within itself an active organization to stimulate, obtain support for, and expand medical education for students and graduates of medicine in the interest of an ultimate better service to the public.

With a committee on education that embraces the deans of the four undergraduate medical schools and representatives of the graduate teaching institutions, and with all the principal institutions for medical teaching and service, and for those devoted to disease prevention and health protection, represented on the board of trustees, the best results of cooperation and coordination are certain to be achieved.

The Association for Medical Education is now organized to offer opportunity to teachers and workers in the medical sciences, whether they are practitioners of medicine or wholly engaged in teaching and research, to participate in the consideration and direction of all matters affecting medical education. It also offers a medium through which the unsurpassed clinical material and research facilities of this metropolitan area may be made readily and conveniently available to all students and graduates of medicine from our own or other countries. The development and special encouragement of teachers of medicine will be one of the important functions of this association.

It is felt by the incorporators that the city of New York is under obligation to assemble and provide resources for the teaching of medicine, in its broadest terms, in a manner compatible with the city's position as an international port and traffic center, and to an extent worthy of its reputation as welcoming hostess to the visitors of the world. Furthermore, the profession feels keenly its duty to pay fitting tribute to the services and contributions of the many leaders of medicine and its allied sciences who have honored this city by their work in healing the sick and controlling disease.

No one medical school or group of special interests, hospitals, laboratories or individuals can command sufficient support to assume the representation or direction of an undertaking in which the entire profession and the public have so large a stake. The spontaneous and immediate support given to the association's plans by the whole medical profession of New York City is a guarantee of the representative and democratic character of the undertaking. To accomplish the purposes of the association, a corporate membership of 300 active workers in the practice and teaching of medical sciences was selected, and from this body a board of trustees, twenty-seven in number, has been duly elected. General members from the profession at large are provided for in the constitution, and will soon be requested to take an active share in the deliberations of the association. Among the incorporators are many who are not at present engaged in teaching, as well as members of the faculties of medical schools and of the attending staffs of both private and public

hospitals. A finance committee has already obtained, within the profession, sufficient funds to provide for the immediate establishment and permanent maintenance of a bureau of information and correspondence at the New York Academy of Medicine, 17 West Forty-Third Street. Reliable data concerning all the facilities that are now or can be made available for teaching purposes will be assembled here; and from this office information concerning the details of courses, dates, fees, qualifications demanded, attendance requirements, etc., will be issued by bulletins and letters. This activity of the Association for Medical Education will be supplementary to the excellent work already well established, and which has been of such great value, by the bureau of clinical information of the Society for the Advancement of Clinical Study.

A committee on education has been most carefully selected, and is now organized to fulfil its difficult functions in a spirit of fairness and firmness. It will be the duty of this committee to prepare plans and standards that shall insure a permanent improvement in the character of medical teaching in New York City; to keep itself informed concerning and to pass on the qualifications of teachers and the character of the courses they offer to graduate students of medicine, and to observe and regulate the manner in which engagements are met by those offering courses under the auspices of the association.

In order that the work outlined by the association shall receive active and sustained consideration, an executive secretary has been engaged to devote his entire time to the development of the project. For this position the executive committee has selected Dr. Henry O. Reik of Baltimore, recently lieutenant-colonel in the Medical Corps of the United States Army and commanding officer of Base Hospital No. 67, American Expeditionary Forces; formerly associate in ophthalmology and otology (1900 to 1912) in the Johns Hopkins University Medical Department, and secretary-treasurer of the International Otological Congress of 1909 to 1912.

The active cooperation of the public health committee of the Academy of Medicine was promptly offered to the association, and a study of the dispensary and hospital teaching facilities of the city has been undertaken by its permanent staff.

What has been a gain to one school or hospital has often heretofore resulted in a loss or injury to the interests of another, and it has seemed essential for the uniform development of all branches of medical science, in every medical school, that a generous provision of funds be actively sought and then so distributed, according to plans matured and agreed to by the association, as to serve the best interests of all institutions and of the public. In forwarding so ambitious a scheme, there must be tactful education of the expectant recipient, the prospective donor and the medical profession as well, in the possibilities of the benefit and the urgency of present needs. A medical education foundation, to meet demonstrated needs, to insure adequate provision for research, teaching, practical training and progressive reeducation of the practitioner, can be made to yield results in safeguarding health and the salvaging of sick and maimed, out of all proportion to the investment. Confidence in the generosity of a well informed public is a fundamental faith of the present day—a faith that has never been betrayed. Special pains will be taken to avoid interference with any other schemata now being made, and with the sources of benefactions now reached by the various colleges and hospitals in the city.

Looking to the comfort and welfare of visiting physicians and surgeons, the association contemplates establishing a central residence or meeting place with provision for social life on lines similar to those developing in London and Paris in anticipation of the need of such professional homes for visiting Americans and colonials. Nor will efforts be spared to obtain close coordination with similar associations of physicians in other cities, under the general central auspices of the Council on Medical Education of the American Medical Association. One of the privileges of the New York association will be to see that those seeking opportunities in clinical, laboratory or field work, which may be better pro-

vided elsewhere than in the metropolitan area of New York, shall be promptly directed to the best teachers and the best facilities wherever they are to be found in this country or in Canada. Cooperation with the committees in London and Paris, which are organizing the medical resources of England and France for the benefit of visitors from the Americas, will be favored, and this may prove to be one means to return in part the courtesies and assistance the American medical officers received without stint from their colleagues during service overseas.

Though New York possesses, to an even greater degree than Berlin and Vienna, most of the elements that made those cities world medical centers, it has not been previously prepared to supply the demands of postgraduate students. Furthermore, a broad distribution from this storehouse of accumulated scientific knowledge that might and should be applied to the prevention of disease and to the healing of the sick has not previously received anywhere in this country its fair share of attention from the genius of American organization and liberality. This association now desires, through proper organization and the procurement and employment of an efficient endowment, to foster such use of this possessed knowledge and facilities as will result in widespread benefit to the whole country. Singleness of purpose, united effort, and personal unselfishness, coupled with unbounded ambition for the advancement of the profession, are certain to win a generous public support.

The officers of the association are: president, Wendell C. Phillips, New York; first vice president, George David Stewart, New York; second vice president, Glenworth R. Butler, Brooklyn; secretary, Haven Emerson, New York; treasurer, Arthur F. Chase, New York.

The association is now in the process of incorporation under the laws of the state of New York, and the trustees who have already accepted their election are: Samuel A. Brown, Emanuel Libman, William Francis Campbell, James Alexander Miller, Rufus L. Cole, Walter L. Niles, William Darrach, William H. Park, Charles N. Dowd, Charles H. Peck, Charles A. Elsborg, Eugene H. Pool, James Ewing, Thomas W. Salmon, John A. Hartwell, Frederick Tilney, Otto V. Huffman, George Gray Ward, Jr., George W. Kosmak and Adrian V. S. Lambert.

Book Notices

TRAITÉ DE PHYSIOLOGIE. Par J.-P. Morat, Professeur à l'Université de Lyon, Correspondant de l'Institut, et Maurice Doyon, Professeur adjoint à la Faculté de médecine de Lyon. Fonctions de Relation. Par J.-P. Morat. Fonctions de Reproduction. Par M. Doyon. Paris, 1918. 9 francs. Pp. 874, with 221 illustrations.

The present volume is the fifth and last of a set dealing with physiology. Unfortunately, the first four volumes did not reach *THE JOURNAL* for review. What is said here, therefore, is necessarily limited to the single volume at hand without reference to the relation of the volume to the others of the set which have preceded it.

The first half of the book deals chiefly with the organs of special sense and ends with a chapter on locomotion and phonation; the remainder is concerned with reproduction, including necessarily a discussion of lactation and the internal secretion of the gonads. In many respects the presentation of the subject matter is different from the usual mode of presentation found in similar English and German texts. The discussion of the special senses is essentially that of years back; for little of great importance has been discovered since the days of Donders, Kühne, Helmholtz, Ewald, Herring and others who were most actively engaged in advancing our knowledge of the special senses. Parenthetically, we express our surprise that the method of retinoscopy, the principal method of correcting errors of refraction, does not even receive mention. The physiology of reproduction and internal secretion of the gonads is presented fully and satisfactorily.

The book is remarkably free from errors. The legends of Figures 69 and 70 ought to be interchanged in order to conform to the facts which the diagram intend to illustrate.

A more serious criticism is the almost complete disregard of the research of American investigators. The most notable example is the failure of the author (Morat) even to refer to the work of Cannon, Carlson, and others in his discussion of the physiologic mechanism underlying the sense of hunger, in spite of the fact that the scientific contributions on this subject which have appeared in various American journals comprise about fifty papers and a monograph of some 300 pages by Carlson. If the first four volumes disregard the results of American investigations as does this volume, the authors must be charged with inexcusable ignorance of the literature or with chauvinism.

HOSPITAL ACCOUNTING AND STATISTICS. Compiled and arranged by William V. S. Thorne, Treasurer and Member of the Board of Managers of The Presbyterian Hospital, New York. Fourth edition. Cloth. Price, \$1.50. Pp. 119. New York: E. P. Dutton & Co., 1918.

This is a standard handbook on the forming of a system of accounting for hospitals that will be simple and intelligent and that will satisfy certified public accountants. Every account that is generally required to be kept in a hospital is classified, and its use is explained. Illustrations make clear the methods of keeping the books, making financial statements, accounting for each of the separate departments, apportioning the expenses, and accounting for reserves and endowments. In addition to financial forms and methods, the book discusses the other hospital records and statistics, illustrating practical forms for use in all the various departments. There is a large number of inserts that are copies of forms in actual use by many of the leading institutions. Hospitals and medical societies have been making an effort to bring about a uniform system of records and reports not only to increase the efficiency in the hospitals but also to facilitate the comparison of financial records and statistics, and medical records and statistics. This book furnishes a practical basis for the adoption of standard records and reports that shall both minimize clerical labor in the hospital and provide a common basis for comparisons between institutions.

DIET IN HEALTH AND DISEASE. By Julius Friedenwald, M.D., Professor of Gastro-Enterology in the University of Maryland School of Medicine and College of Physicians and Surgeons, Baltimore, and John Rahrba, M.D., Professor of Diseases of Children in the University of Maryland School of Medicine and College of Physicians and Surgeons, Baltimore. Fifth edition. Cloth. Price, \$6. Pp. 919. Philadelphia: W. B. Saunders Company, 1919.

The fifth edition of this most valuable work is fully up to the standard of previous editions. It is an encyclopedia on diet. The authors explain that the stress of war work prevented the inclusion of any literary references prior to January, 1918. A considerable space is occupied by tabular matter and discussion relative to alcohol and various alcoholic products. Very possibly this may be greatly abbreviated in future issues, since the analysis of thirty or more brands of beer can have but slight interest for those who have no beer at all. The book presents briefly and particularly all of the well known dietary methods; for example, those of Leube, the Karel method, the Sippe diet, the Prochnick diet for pregnancy, and in fact a series of diets for every possible illness, institute or individual. Numerous supplementary tables add to the value of the text.

THE ORGANS OF INTERNAL SECRETION: THEIR DISEASES AND THERAPEUTIC APPLICATION. A Book for General Practitioners. By Ivo Gorkie Goh, M.D., M.R.C.S., Neurologist, Birmingham, Second Western General Hospital. Cloth. Price, \$2.50. Pp. 274. New York: William Wood & Co., 1919.

In spite of the statement in the preface to the second edition of this book, there is no evidence that "the entire book has been carefully revised and brought up to date." It is virtually a reprint of the first edition. Aside from the addition of several paragraphs and one new chapter, it contains the same misinformation, contradictions, misleading statements and typographic errors as in the first edition, and is in the same excellent literary form. The review of the book printed by *THE JOURNAL*, March 23, 1918, p. 876, applies as well today

to the new edition as it did when the book first appeared, with the exception that the page references given in the first review are necessarily not the same. The chapter on "The Endocrine Glands and Nervous Disorders" which has been added to the new edition conforms in style and content to the remainder of the book previously published.

THE SOUL IN SUFFERING: A PRACTICAL APPLICATION OF SPIRITUAL THERAPY. By Robert S. Carroll, M.D., Medical Director, Highland Hospital, Asheville, North Carolina. Cloth. Price, \$2. Pp. 241. New York: The Macmillan Company, 1919.

Dr. Carroll endeavors to condense in his little book the experiences of many years spent in contact with those sick in body, mind and soul. "Religion and medicine," he says in his introduction, "have stood too long on opposite sides of the couch of suffering, forgetting, one the body and the other the soul, and both, the mind." Assuming that the mission of suffering is to build character, he endeavors to bring together the practical benefits of modern scientific medicine and the aspirations of religion. His book can be read with pleasure and profit by physicians and patients, and by any others endeavoring to solve that great problem of human existence, pain.

Proportionate Dose of Quinin Required to Produce the Same Results in Treating Malaria in Children of Different Ages as in Adults

DR. C. C. BASS, New Orleans: No two textbooks on malaria give the same treatment, unless one copies from another. The dose for adults is stated as being from 10 to 40 grains, but that for children is very indefinite. There are two ways to control malaria: one by destroying mosquitoes, the other by controlling the parasite in man. Malaria can be eliminated from a locality by whichever means is most practical. In large areas the disinfection of persons is more practical than ditching and draining. In an area of the Mississippi Valley, with a population of 31,459 persons, the highest percentage of infection was in the 5 to 10 years group, and most malaria was in persons under 20 years of age. By ordinary means of treatment few persons are thoroughly disinfecting, and will subsequently relapse. Relief of clinical symptoms does not mean disinfection.

Children under 1 year of age should be given 0.5 grain; at 1 year, 1 grain; 2 years, 2 grains; 3 and 4 years, 3 grains; 5, 6 and 7 years, 4 grains; 8, 9 and 10 years, 6 grains; from 11 to 14 years, 8 grains, and at 15 years the adult dose, 10 grains. Ten grains of quinin every night for eight weeks disinfects 90 per cent. of all infected persons. The remaining 10 per cent. have to receive three 10 grain doses a day for three or four days, and later 10 grains a day for eight weeks. The amount of quinin taken is the only criterion as to disinfection of the infected individual.

DISCUSSION

DR. DOUGLAS VANDER HOOFF, Richmond, Va.: The physician generally thinks he has done his duty when he has relieved

symptoms. For the sake of the community the patient has to be disinfected. A good deal of harm is done by giving proprietary medicines containing small doses of quinin, by which means the malarial parasite becomes, to a certain degree, resistant.

DR. JACOB DIXER, New York: There is little difference between quinin sulphate or chlorid, except as to palatability. In giving quinin to children, one should not use condensed milk, as that tends to create a distaste for milk and deprive the child of nourishment. The stimulation of taste buds is caused by solution. Therefore if given in an insoluble form, such as alkali, salicylate or tannate, it will accomplish the purpose just as well as when given in some syrup. The latter as sold in drug stores often contains only 1 grain per dose.

DR. HORATIO WOOD, Philadelphia: The question of dosage for children opens an interesting problem. Dr. Bass bases the dosage on the age of the child. Cowling and Young approximate the weight of the child. A physician should be able to guess the weight of the child, and this is the proper way. Where therapeutics is carried out in such a wholesale manner, this might be difficult. It was interesting to hear that insoluble salts are absorbed as readily as soluble salts. In regard to disguising taste, sweet disguises bitter. The taste of quinin can be disguised by putting it in a suspension of gum acacia. I find that methyl thionium has a decided antiperiodic effect, especially against the gametes. It may be found that the parasites become quinin fast by developing a resistance.

DR. J. B. WHITE, New York: Two things are important: the treatment of the paroxysm and the prevention of recurrence. Small amounts of quinin can be given before the paroxysm, to allow of assimilation, and from 30 to 40 grains during the paroxysm. With a mixed paroxysm, such as double quotidian or double tertian, 20 grains, three times a day is better.

Influenza and After

DR. THOMAS F. REILLY, New York: In most of the acute diseases, the subsidence of the acute symptoms is commonly followed by a return to normal and freedom from symptoms. In the influenza of this year, however, one had to deal with an almost diametrically opposite clinical picture. In about one half of the cases a syndrome or group of symptoms, materially different from that observed during the course of the disease, appeared on the subsidence of the acute symptoms. These sequelae were often more annoying and resistant to treatment than the primary disease. In some cases one set of symptoms was present, in another, several independent groups. Almost every portion of the body and every organ was affected. First and foremost among symptoms was the cough. This frequently resembled whooping cough; the patient coughed continuously until exhausted. The cough often produced nothing but small quantities of tough mucus. Another cause of trouble was the existence of various painful and parasthesic areas in the chest. Pain and cold feelings between the scapulae were associated with enlarged glands or exaggerated hilum shadows. Sometimes they were lower down the back, radiating to the abdomen. Occasionally there was involvement of the diaphragmatic pleura, with tenderness at the junction of a line from the tenth costal cartilage to the parasternal line. In many cases there was associated suppurative appendicitis, with localized pain and high leukocytosis. Nausea and vomiting were present. Headache was often very persistent. Dyspnea and palpitation on exertion were common, and there was often arrhythmia. Associated symptoms were: sweating of hands, night sweats, weakness, loss of memory and energy. Fatigue was easily induced. Often there was pain over the heart. One case of aortitis following influenza was noted. Digestive disturbances were common, but in leptemia, if one excepts hyperchlorhydria. Ulcer cases were prone to relapse. Albuminuria and impairment of vision were occasionally noted. A persistent subileal temperature was not uncommon. Disturbances of the nervous system were melancholia and sleeplessness, the latter causing much worry to the patient. Loss of taste and smell was tem-

porarily noted. Falling out of the hair was frequent. Treatment was directed to controlling the cough and for this application of a 2 per cent. solution of silver nitrate to the fauces, nasopharynx and nose was effective. Occasionally, codein, $\frac{1}{4}$ grain, with heroin, $\frac{1}{16}$ grain, was necessary. Creosote and terebene were of value. In cases of enlarged glands sodium iodid, 2 grains, or syrup of ferrous iodid was used. Calcium iodid, 2 grains, four times a day, was valuable, particularly in the treatment of mediastinal glands with cough. In the group representing the sympathetic syndrome—weakness, sweating, etc.—the following was used: extract of the suprarenal glands, 3 grains; arsenous oxid, $\frac{1}{16}$ grain; strychnin, $\frac{1}{320}$ grain, and quinin sulphate, 2 grains, one capsule before meals. This combination gave good results. Patients who suffered cardiac neuroses were ordered to rest for a week or two. For the headaches of sinus origin, a cleansing alkaline solution was used. An epinephrin spray brought relief. Change of climate was the sovereign remedy. In cases of continuous or relapsing temperature, foreign protein injection, by means of government lipovaccines, was instituted with good result. For the digestive disturbance, a diet suited for hyperchlorhydria was advisable. Alcohol, in the form of red wine or whisky and water, did much to combat depression. The eyes returned to normal without treatment. The myringitis, which was often persistent, was treated best with a 2 per cent. solution of silver nitrate. Some cases seemed refractory to any treatment.

General Treatment of Influenza

DR. NOBLE P. BARNES, Washington, D. C.: Patients should be kept in a light, airy room, free from dust. Antiseptic sheets should be hung over the door, and sputum cups in paper bags should be used. Roentgen-ray examination should be made and the blood pressure taken. After establishing the diagnosis, frequent examinations should be avoided. Immunizing vaccines should be used, as this disease fails to awaken body response, as shown by leukopenia and asthenia. In the beginning stages of pneumonia, the intravenous injection of typhoid protein is a safe procedure. It is contraindicated beyond the third day of the disease and in myocardial insufficiency or endocarditis. The reaction is not specific, but depends on the protein content. The patient should be put to bed with the first symptoms, and kept there until four days after subsidence of temperature. Then, if the heart and lungs are normal, he can get up. Diet could then be to full digestive capacity. Coal tar and depressing drugs should not be given. The one essential measure above all others is prolonged rest in bed.

DISCUSSION

DR. F. M. PORTINGER, Monrovia, Calif.: I do not think the tuberculous patient is susceptible to influenza. Among 100 patients in one sanatorium there was not a single case of influenza. There was no quarantine, but care was taken. As regards cold air, there is nothing to be gained by subjecting the patients to cold. They do not require an absolutely aseptic environment. It can be much lower than 72 F. In regard to changes of temperature, a marked variation between morning and night is beneficial to patients and acts as a stimulus, as long as the body cells react well.

DR. DORR, A. C., Jr., Richmond, Va.: No one has ever convinced me of the value of vaccines in a disease that does not become permanent in the body. Influenza seems to peak and recede rather quickly. There may be danger of producing reactions by the vaccine and subjecting the individual to more discomfort. As to isolation of patients in separate rooms, generally patients in private rooms do better than the convalescents. The high mortality was due to enforced isolation of cases, with subjection to mixed infection.

DR. TAYLOR, L. KIRBY, New York: I noticed one sign in patients with even mild influenza. They had enlargement of Stern's duct, with redness of the tip of the tongue, which stuck out like a cock's comb. Nausea was a distressing feature in the early part of the epidemic. This was well controlled with from 3 to 5 grains of chloral.

Convulsions and Epilepsy.—Morse has looked up, as far as possible, the condition of the babies and children with convulsions whom he has seen, including only those cases in which the convulsions were the primary cause for his attendance and excluding all those cases in which there were any evidences of acute or chronic cerebral disease. Satisfactory reports have been obtained regarding 107 children. Morse has divided these cases into four classes: (1) cases in which the convulsions were associated with evidences of spasmophilia; (2) cases in which the convulsions occurred in the course of whooping cough; (3) cases in which there was a single convulsion or a series of convulsions at the onset of some acute disease or with an attack of acute indigestion; (4) cases in which there had been repeated convulsions during a considerable period or in which there had been repeated attacks suggesting petit mal. It is evident that convulsions which are a manifestation of spasmophilia are not likely to eventuate in epilepsy. Convulsions which occur in the course of whooping cough must always be regarded seriously, as they are quite likely to be followed by epilepsy later. Single convulsions or a series of convulsions occurring at the onset of an acute disease or with an attack of acute indigestion are less likely to be followed by epilepsy than are repeated convulsions during a considerable period or repeated attacks suggesting petit mal. Repeated attacks which would be classified as petit mal, or which suggest it, are just as likely to eventuate in epilepsy as repeated attacks of general convulsions. Nothing can be told from the nature of the early attacks as to the nature of the attacks when epilepsy develops later. When an injury to the head has directly preceded the onset of the attacks or there is no apparent cause for the attacks, epilepsy is more probable than when there is an apparent cause, such as indigestion, for each attack. The presence of an apparent cause for the attacks does not, however, exclude epilepsy. The longer the attacks have persisted, the more probable is the diagnosis of epilepsy. General impressions, which cannot be explained, have a certain value in diagnosis. Finally, and most positively, Morse says, there is no way to determine immediately when a baby or child has a convulsion, or has had repeated convulsions or repeated attacks suggesting petit mal, whether it has epilepsy or whether it will develop it later.

Postinfluenzal Encephalitis. From his observation of eight cases Heiman differentiates three main forms, depending on the severity and the most prominent symptoms: (1) Irritable; (2) lethargic and (3) lethargic with paralyses. There is no specific therapy. Good results have been reported from lumbar punctures, but Heiman has not found this procedure of special benefit.

Constipating Qualities of Orange Juice. Observations made by Gerstenberger and Champion on a normal infant of 10 months of age to ascertain the position as a cathartic or laxative of orange juice to an equal amount of a 10 per cent.

sugar solution composed of 6.5 per cent. glucose and 3.5 per cent. sucrose show in one period no difference between the two solutions, and in the other period a relative laxative advantage of the sugar solution over the orange juice, or better, a relative constipating ability of orange juice as compared with the effect obtained with the 10 per cent. sugar solution. During the sugar solution period anywhere from 95.71 to 96.53 per cent. of the water output went by way of the kidneys, and from 4.29 to 3.47 per cent. went through the intestines, while in the case of the orange juice from 97.15 to 97.25 per cent. of the fluid output went by way of the kidneys, and from 2.85 to 2.74 per cent. by way of the intestines. In other words, orange juice, relatively speaking, has been less laxative than a 10 per cent. sugar solution when given in doses of 15 c.c., six times in twenty-four hours. This observation confirms practical experience that orange juice in the maximum amounts ordinarily used has more of a constipating than a laxative effect, and therefore should only be used as an antiscorbutic or as a diuretic, but not as a laxative, and especially not for children who are already constipated. These observations also point to the important rôle that diuresis may play in the production of constipation, and it may be possible that some of the cases of constipation in infants supposed to be due to an abnormally long retention of the feces in the gut and a consequent too complete absorption of water in the large intestine are primarily due to the presence of a factor that causes an abnormal increase in the excretion of water through the kidneys.

Lactose, Fat and Protein Content of Woman's Milk.—Dennis and Tallott found that there is a rapid increase of lactose during the first few days when colostrum changes into milk, and a further increase as lactation progresses. The reverse is true of protein which after the first rapid decrease during the change from colostrum into milk tends to further decrease during the course of lactation. After the colostrum period there does not seem to be any relation between the stage of lactation and the amount of fat in the milk. There is usually a higher percentage of lactose at the beginning of a single nursing than at the end. Although this difference may be 1 or more per cent., it is usually less. It is almost the rule for the percentage of fat to be much higher at the end of nursing than at the beginning. There is very little, if any, difference in the protein. The milks taken simultaneously from both breasts of the same woman tend to have the same composition, but often vary in respect to the percentage of fat. Toward the middle or later afternoon the volume of milk in a woman tends to diminish. The percentage of fat is, as a rule, higher at midday or midafternoon, than at other times of day.

Sporadic Case of Meningitis Due to Carrier.—Shaw cites the case of a 5 month old breast fed infant living on a farm who developed cerebrospinal meningitis. There was no record of any previous cases in the locality. On account of the isolated location of the farm it was possible to ascertain and examine every person who had come to the house for a week previous. One of the visitors was the uncle of the baby, a man, 33 years of age, who enlisted in the army in April, 1917, and went to France in August, 1917. He returned to this country in January, and fondled the baby January 28. A few days later the baby was taken ill. Examination of the spinal fluid confirmed the diagnosis of meningococcus meningitis. Postnasal cultures made from eight persons were negative except those from the soldier, and the meningococci obtained from him were agglutinated by the fluid obtained from the spinal fluid of the baby and were also proved to be identical by culture. A point of interest is that the organism still persists in this carrier four months later. He has used irrigations of all kinds and has been under the treatment of a nose and throat specialist, but the meningococci resist all bacterial procedures.

Fat Metabolism.—This study of fat metabolism presents observations on children whose diet contained a large proportion of solid food. It gives the findings as to fat percentage and distribution in the stools of a number of children receiving a mixed diet and the fat retention of these children.

Need for Broader Program in Campaign Against Tuberculosis. G. T. Palmer, Springfield, Ill.—p. 268.
*Industrial and Agricultural Community for Arrested Cases of Tuberculosis. H. A. Pattison, New York.—p. 276.

Cooperation in Tuberculosis Campaign.—One of the suggestions made by Lyman in this paper is that the health record of every man be filed with the United States Public Health Service and with the state board of health of his own state. Lyman seems to be convinced that in the near future we will adopt some form of military service for all young men so that we may have all of them as they reach the age of 18 under military training for six months or more. From the standpoint of national health that would mean a chance for a complete physical study and, if need be, corrective physical training during this period for every young man.

Industrial Community for Arrested Tuberculosis Cases.

The proposition offered by Pattison is the development of industries around a community for the sake of that community, which is to be made up chiefly of arrested cases of tuberculosis among soldiers, sailors and civilians. Those soldiers and sailors who are substandard physically because of other forms of disability than tuberculosis would not be debarrd, but the totally disabled, epileptic or mentally deranged could not be received. There would also be perfectly well people occupying executive positions or placed in jobs such as were required to keep processes going. The community should be complete within itself, yet in immediate touch with other neighboring villages and cities. Topographically, it should be well situated on elevated, hilly ground with several acres of woodland, and, if possible, with an active but small river winding through it. The tract should be located within 100 or 200 miles of some large city and not in an isolated corner of a far Western state. It should be on a line of railroad and preferably a main line, with ready accessibility to raw materials and markets. The village proper should be laid out according to modern ideas of town planning to care for 500 or 600 population almost immediately, with possibilities for expansion to 4,000. Its general features, in Pattison's opinion, should conform to those of other American towns rather than to English garden cities. While the homes should be diverse in design, the architectural *tout ensemble* should be harmonious and artistic. The department of health should be a model in every respect and be given a place of honor equal in importance with the industrial phases of the community. Conservation and restoration of man power would be given first consideration. There would be diagnostic, pathologic and research laboratories. The director of the department would be given as many medical assistants and public health nurses as the growth of the community required. Every person, man, woman or child, who came to take up residence would be given a complete physical examination, including stereoscopic chest plates and biologic tests. Periodic reexaminations and special examinations when indicated by the appearance of symptoms would preserve a life history of the human

machine," making it possible to reduce greatly the morbidity and mortality rates in comparison with other industrial towns of like size. Under such conditions an unusual opportunity would be offered for the development and application of psychologic, trade, efficiency and fatigue tests. The population would be drawn largely from the sanatoriums of neighboring states. School training courses would prepare men and women to give occupational therapy and prevocational training in sanatoriums thus sending forth missionaries to prepare sanatorium patients for the colony.

- Diagnosis of "War Psychoses." G. E. McPherson, Medfield, Mass., and L. B. Holman, Baltimore—p. 207.

Experimental Compression of Spinal Cord.—The experimental work reported on by Ayer was done on cats. The results showed that paraffin may be injected into the epidural space in cats, with resultant compression of the cord and symptoms of incomplete transverse myelitis. Spinal fluid obtained from below the area of compression usually shows marked increase in protein content, at times is yellow and clots spontaneously. The greater the amount of protein the more likely is the fluid to clot. Fluids obtained from the subarachnoid space above the area of compression are invariably normal or nearly normal. The pathologic fluids obtained are entirely comparable with (1) the *syndrome de coagulation anasique et de anthronurie* of From, and (2) the syndrome of Noone, both characteristic of spinal cord compression in man.

Colloidal Gold Reaction in Psychoses. An analysis is made by Rawlings of the colloidal gold reaction in 498 cases of various psychoses in which there was suspected a nervous syphilis from the clinical findings of pupillary changes, exaggerated or lost reflexes, speech defects, histories of early cardiovascular involvement or apoplexies; with miscarriages, stillbirths, defective mental development or more frank syphilitic manifestations in the immediate relations. No case was encountered which did not show either a positive Wassermann reaction of the serum with suggestive neurologic symptoms, or neurologic symptoms which made dependence on a negative serum inadvisable. The following results were obtained: One hundred and three patients gave parietic curves with positive Wassermann reactions of either serum or spinal fluids; or both; ten gave suggestive curves of incipient paresis with negative Wassermann reactions of serum and spinal fluids; fifty three gave syphilitic curves with positive Wassermann reactions of either serum or spinal fluids; or both; 118 gave syphilitic curves with negative Wassermann reactions of serum and spinal fluids; 209 patients gave negative gold reactions, fourteen of whom showed positive Wassermann reactions of the serum and three positive Wassermann reactions of the spinal fluids; five gave atypical curves, several of these being treated cases. Rawlings concludes, therefore, that the spinal fluid of cases of dementia paralytica causes a quite characteristic curve with the colloidal gold solution which is of such frequent occurrence as to be diagnostic. In seven cases the diagnosis was confirmed by necropsy. The spinal fluid of taboparalytics may normally give syphilitic curves or rather low parietic curves. Cerebrospinal syphilis gives a curve which may be considered diagnostic. Syphilitic curves with negative Wassermann reactions of serum and spinal fluids may be obtained in cerebrospinal syphilis, the reaction not necessarily being due to a dialyzable

substance other than syphilitic. The gold curve is of value in clearing up the etiology of old arteriosclerosis with negative Wassermann reactions; necropsies having demonstrated a syphilitic type of vascular lesion in cases giving syphilitic curves and a simple senile degeneration of the vessels in cases giving negative gold reactions. It is of interest that five cases of Huntington's chorea gave negative gold reactions, one of which, however, demonstrated pathologically an inactive moderate taletic involvement of the lumbar regions. The syphilitic curve may be of value in clearing up the etiology of mental deficiencies after an active syphilitic process has ceased and antibodies have disappeared from the body fluids. The globulin reaction is rather uniformly strongly positive in paresis and a fair proportion of syphilis, but there appears to be no definite relationship between the curve and the strength of the reaction.

Pituitary Gland in Epilepsy.—Tucker believes that there is a definite relation between the undersecretion of the pituitary gland and a group of periodic convulsive attacks usually termed epilepsy; that this group is divided into a chronic hypopituitary type and a transitional hypopituitary type by both clinical and roentgenographic evidence; and that pituitary gland feeding has a markedly beneficial effect occasionally leading to cure.

Postdiphtheritic Ataxia.—The three cases reported by Wilson are of interest from the type of sensory loss which they show, the loss of sensation being exactly similar to that seen in the combined sclerosis of pernicious or severe secondary anemia. The subjective symptoms which were complained of in these cases were of the same character that is so common in anemia. All three patients had paresthesias in the hands and feet, and all showed a loss or marked impairment of the sense of position and of vibration; in two of the cases with preservation of touch sense there was impairment of the ability to recognize the two points of a compass. Wilson believes he is justified in placing the lesions which account for the sensory loss in these cases in the posterior columns of the cord and not in the peripheral nerves.

Etiology of Yellow Fever.—Examinations of fresh blood from yellow fever patients by means of the dark field microscope, made by Noguchi in more than twenty-seven cases, revealed in three cases the presence of *Leptospira icteroides*. The injection of the blood into guinea-pigs from two of the three positive cases induced in the animals a fatal infection, while the blood from the third positive case failed to infect the guinea-pigs fatally. Stained blood film preparations from the corresponding cases were also examined, but the percentage showing the leptospira in the blood was no greater than that found by examination in the fresh state with the dark field microscope. Examinations of the urine by dark field microscope and by inoculation into guinea-pigs were totally negative in thirteen cases, including many convalescents, but in one case one of the guinea-pigs inoculated with 10 c.c. of the urine came down on the fifteenth day with suggestive symptoms (suspension of jaundice, and some hemorrhagic and parenchymatous lesions of the lungs and kidneys). This specimen showed no leptospira by dark field examination. In experimental infection of guinea-pigs with *Leptospira icteroides* the blood became infective in many instances forty-eight hours after inoculation, and was always infective after seventy-two hours. The liver and kidney become infective simultaneously with the blood. Detection of the organism by means of the dark field microscope has seldom been accomplished before the fifth day. The organisms are most abundant on the sixth or seventh day, but become fewer or completely disappear before death. In the meanwhile the number of organisms increases in the liver and kidney, from which they disappear as the jaundice and other symptoms become aggravated. When death occurs these organs seem to have lost most of the leptospira, and positive transfer by means of them is less certain. At the later stage of the disease the blood is often free from the organisms and ceases to be infective.

Etiology of Yellow Fever.—By the inoculation of guinea-pigs intraperitoneally with the emulsions of kidneys from wild rats and mice captured in Guayaquil, Noguchi found that 67 per cent. of the wild rats tested harbored in their kidneys a leptospira which produced in guinea-pigs symptoms and lesions identical with those produced by *Leptospira icterohæmorrhagiae* derived either from patients suffering from infectious jaundice in Japan or Europe or from wild rats caught in New York. Guinea-pigs inoculated with killed cultures of the Guayaquil strains of leptospira proved to be resistant to a subsequent infection with heterologous as well as homologous strains of *Leptospira icterohæmorrhagiae*. It is concluded, therefore, that the leptospira isolated from the kidneys of wild rats and mice in Guayaquil belongs to the group of *Leptospira icterohæmorrhagiae* and differs from *Leptospira icteroides* in its immunity reactions.

Intestinal Obstruction: Absorption of Toxic Material.—This study was undertaken by the Dragstedts and others to determine the factors involved in the absorption of toxic materials from the intestine. It was found that if isolated intestinal loops were washed with water and ether previous to closure many animals survived the operation and never displayed any toxic symptoms, and that these loops when subsequently removed and examined contained great numbers of bacteria. Experiments made to determine whether the growth of bacteria and the production of the usual toxic substances in closed intestinal loops were prevented by the previous use of antiseptics established the fact that this is impossible even in a short piece of intestinal tract. They indicate that the part played by ether is not that of a bactericide and that it does not markedly inhibit the production of toxic materials in intestinal loops. The absorption of these toxic substances is for some reason prevented. It is possible for many times the lethal dose of these poisons to remain in closed loops of the jejunum or colon without the production of toxic symptoms. Apparently, simple astringents with no

germicide properties are just as effective in preventing the symptoms of toxemia in dogs with closed intestinal loops as are the antiseptics. It was evidently the astringent properties of the ether and the other chemicals rather than their bactericidal properties that account for the results produced. It was also determined that the mucosa of the alimentary tract does not elaborate an internal secretion which is necessary to life, or a secretion which could be disturbed by the conditions of acute obstruction so as to account for the symptom complex of that condition. The substances responsible for the toxemia in acute obstruction are produced by the action of intestinal bacteria on proteins or their split products. An injury to the intestinal mucosa, particularly that resulting from disturbances of the blood supply to the intestine, greatly facilitates the absorption of these poisons.

Studies on Pneumococci.—Clough reports the results of a study of nine strains of pneumococci agglutinating with antipneumococcus serums of all three types (Nos. I, II, III). Seven of the strains were the cause of serious or fatal infections in human beings. The virulence of the strains varied greatly. In general, the strains were found to be serologically distinct, though some interrelationships existed between several strains. A mutation occurred in one of the strains, while it was under observation. On isolation this strain had the cultural reactions of a typical pneumococcus, and had the phagocytic and agglutinating reactions of an atypical Type II. After six months' cultivation on blood agar its serologic reactions changed, and it became actively phagocytized and agglutinated in antipneumococcus serums of Types I, II, III. Its cultural characteristics also changed, and it became bile insoluble, did not ferment inulin, and caused precipitation in glucose-acetic fluid agar. At this time it caused an intense green discoloration at the base of the blood agar slants around the water of condensation. By repeated animal passages this strain was three times made to revert abruptly to its original form (atypical Type IIa), both in cultural and serologic reactions. An immune serum was prepared to each form of the strain, and each serum acted strongly on the homologous form, but was without action on the heterologous form of the strain. Clough believes that this mutation suggests that these pneumococci reacting with all three types of antipneumococcus serums may represent primitive, relatively undifferentiated forms from which the fixed types may have arisen.

Oxygen in the Venous Blood.—Clinical experience agrees with the experimental results obtained by Lundsgaard; a bodily and mentally resting anemic patient usually does not show any marked reaction from the circulation, until the hemoglobin percentage has fallen below 30. In patients whose hemoglobin is below that value an increased pulse rate and palpitation of the heart even at rest is evidenced.

Potassium Iodid in Experimental Sporotrichosis.—The experiments reported on by Davis indicate that potassium iodid given to animals for eight days previous to inoculation with sporotricha will have no effect in inhibiting or preventing the infection. Also, when given simultaneously and for a week following the inoculation, the infection appears to continue without interruption. When the potassium iodid is continued indefinitely, the lesions heal, becoming hard and

Treatment of Lymphatic Leukemia with Benzyl Benzoate.—Haughwout and Asuzano report on the use of benzyl benzoate in a case of lymphatic leukemia in which the disease had been of at least two or three years' standing. The results were good but the authors make no claim for the therapeutic efficacy of the drug, except that it is evidently free from the evil tendencies and can be administered indefinitely and with effectiveness to a patient in an advanced stage of the disease, without deranging the alimentary tract or kidneys. The initial dose of benzyl benzoate in this case was 10 drops of the 20 per cent. alcoholic solution, in water, three times a day, after meals. Later the dose was reduced to 5 drops, but when former symptoms recurred the original dose of 10 drops was resumed. Improvement in all the symptoms followed; the patient gained in strength, eats well, sleeps well and is free from discomfort or pain.

Intrathoracic Goiter, Showing a Thyrotoxicosis.—In the case cited by Leiner, Forchheimer's treatment of quinin hydrobromate and ergotin resulted in improvement, but when it was stopped a relapse occurred, both subjectively and objectively. When the patient received ovarian extract some improvement was noticed in regard to her hot flushes and tremor. Then she was given 5 grains of thymus extract, three times a day. No exacerbation of her thyrotoxic symptoms was observed.

- *Therapeutic Efficacy of Antitetanus Serum: Site of Injection. R. Kobayashi.

Therapeutic Efficacy of Antitetanus Serum.—Comparative studies of the therapeutic administration of antitetanus serum by intravenous and subarachnoid injection were made by Kobayashi. In the treatment of the experimental tetanus in the rabbit which had received a dose of the toxin sufficient to kill it in from 5 to 8 days, all the animals that had been given the serum within twenty-four hours after the injection of the toxin into the vein recovered. There was, however, a difference between those animals that were given the serum into the vein and those injected into the subarachnoid cavity, for with the former the minimum therapeutic dose was ten times as large as that with the latter. When the toxin was injected into the subcutaneous tissue instead of into the vein, and the animal was given the serum within twenty-four hours, all the animals recovered, but this time the minimum therapeutic dose with the intravenous administration was 300 times as large as that with the subarachnoid administration. The minimum therapeutic dose with the cases that were given the serum into the subarachnoid cavity after twenty-four hours from the injection of the toxin either intravenously or subcutaneously was just the same, but the intravenous administration of the serum differed within a wide range, for the subcutaneous injection of the toxin was just ten to thirty times as large as that with the intravenous injection of the toxin. The immune serum was found powerless when it was given either subarachnoidally or intravenously after forty-eight hours from the injection of the toxin intravenously. By the subarachnoid administration of the immune serum forty-eight hours after the injection of the toxin subcutaneously, a little efficacy was found to be manifested.

Local Anesthesia of Uterus.—By means of the vaginoscope the orifice of the uterus is exposed and the anesthetics are injected with a 5 gram syringe at posterior, anterior and bilateral points about the border of the cervix and the vaginal wall. The needle is driven toward the base of the cavity for a distance of 2 mm. and the injection is made very slowly. The operation is begun in about five minutes after the operation. By this method all the operations on the mucous membrane of the vagina and the uterine cavity may be carried out without applying general anesthesia.

- *Three New Amputations of Foot, Each Conserving the Gait. C. E. Corlette.—p. 479. To be continued.
- Three Cases of Aplastic Anemia. G. F. Renard.—p. 485.

Amputation of Foot Conserving Calcaneal Tread.—One of the three operations devised by Corlette was done on a boy whose leg had to be amputated at the junction of the middle and lower third. The whole of the foot in front of the talus on the other side was crushed. The mangled mass was cut away with every possible care to retain viable tissue. There was no material for an upper flap, and there was not enough sole left to cover the surface exposed. With a pair of large bone shears Corlette made a horizontal section of the talus and removed the distal fragment. Next, he did a subcutaneous division of the Achilles tendon. Then he cut through the base of the sustentaculum tali, and cleared the soft tissue from the top and sides of the calcaneus. The shears were used to make a horizontal section of the calcaneus, the upper convex surface being removed as far back as the blades could reach, and a plane surface was left. The residual distal part of the calcaneus was then pushed forward as far as possible; the front of it, including the greater process, was sheared off, and the remaining fragment was fitted in its advanced position beneath the talus, with a view to getting bony union. No wiring was attempted. In point of fact, the primary intention of all this was to get a flap and this was successfully accomplished. The removal of the anterior portion of the calcaneus gave length to the plantar flap, and the horizontal section of the talus and the calcaneus, with removal of bone, shortened the vertical measurement, lessening the distance the flap had to reach. The net result of the procedures undertaken was a very satisfactory viable covering for the gap in front, with a well elevated situation for the cicatrix, away from all risk of pressure. The result was perfect.

In a second case this procedure was altered somewhat. Corlette first removed all that portion of the foot anterior to the medi-tarsal joint, leaving the skin intact at the line of demarcation. Horizontal section of the head of the talus was done by an osteotome. The Achilles tendon was cut subcutaneously. The sustentaculum tali was cut off and removed. The various ligamentous attachments of the calcaneus to the talus were divided, and the under part of the talus was removed further back. The calcaneus was horizontally bisected just above the level of the greater process in front. The section of the calcaneus was carried back near to the insertion of the Achilles tendon so that the upper fragment included the smooth surface of bone above the insertion of the tendon. The greater process of the calcaneus, i. e., the part anterior to the groove which provides attachment for the interosseous ligament was removed. The calcaneus was then pushed forward as far as it would go beneath the talus. The skin flaps were cleared of granulation tissue, shaped and sutured. The result in this case was also good.

Three Cases of Aplastic Anemia.—Rennie suggested that aplastic anemia in young persons is the result of the exhaustion of function of a bone marrow congenitally defective in power of endurance, while in older persons it is the result of some poison or poisons which, acting on the bone marrow, destroys its function and so leads to the death of the patient. A pathologic hemolysis as an essential part of this syndrome is not proved.

Electrons and Rays in Therapeutics. M. Van de Maele—p. 301.

Meningeal Hemorrhages After Contusion of Skull.—Guillaumin declares that meningeal hemorrhage is much more common than generally recognized with simple contusion of the skull or apparently mere scalp wounds. He describes thirteen cases from his own experience. The symptoms were very vague, but lumbar puncture cleared up the diagnosis and aided in recovery. Even where there is a hematoma in connection with the meningeal hemorrhage it may subside completely under repeated lumbar puncture and be resorbed spontaneously. In one of his cases pronounced aphasia from this cause retrogressed spontaneously. To open the intact dura mater is not always a harmless intervention and should be avoided when possible. He also warns of the eventual danger from chloroform, ether or nitrous oxid with meningeal hemorrhage. Local anesthesia alone should be used in exploring the skull, as the vasodilation produced by general anesthesia may increase or induce the hemorrhage. The only fatality in his series was in a case in which ether had been given. He warns further that lumbar puncture, withdrawing a rather large amount of fluid, had better not be done at first as the reduction in the pressure might cause some clot plugging a vessel to drop off, and thus might set up a new hemorrhage. In the succeeding days, however, lumbar puncture has decided therapeutic value, reducing the pressure and evacuating the toxic products of the hemolysis. Among the symptoms which suggest meningeal hemorrhage are slight mental confusion, bilateral inversion of the plantar skin reflex, true defensive reflexes like those of the frog, and a salowness from the hemolysis.

Physiotherapy After Injury of Peripheral Nerves.—Stouffs describes the preferable measures needed to act favorably on the injured nerve, on the paralyzed muscles, and on the psychomotor centers of volitional control.

Spontaneous Pneumothorax.—Fredericq found the heart pushed over to the left in a young soldier with a mild pulmonary tuberculous lesion. He had been taken with a sudden pain in the right kidney region, spreading to the shoulder. There was no vomiting, no dyspnea, no cyanosis, no cough, but radiocopy showed pneumothorax, the right diaphragm immovable, the right lung collapsed. The absence of decisive symptoms in this and in a second case in a girl of 17 suggests that unrecognized pneumothorax may be comparatively common. In the girl, both the pneumothorax and a focus of purulent pleurisy had escaped discovery at the clinical examination. The resonance on percussion seemed normal on both sides, and râles were pronounced also on both sides. She succumbed to progressive asphyxia without a clear diagnosis having been made.

Antipneumococcus Serum. C. Truche—p. 323.

Instrumental Orthopedics.—Bidoz affirms that if the disabled person has anywhere in his body a segment which he can move at will, it is possible to devise some apparatus to utilize this power of movement and adapt it to some useful purpose. Each case has to be studied individually and to make the most of its possibilities requires a combination of

power of observation, mechanical skill and knowledge of anatomy and physiology. As an example of what it is possible to realize by this means, he says that a paraplegic by using the up and down and sideway movements of his shoulders might be able to make movements of progression. Jalaguier's comment on Bidon's apparatus is that they are so complicated their use will necessarily be extremely restricted.

Cancer a Ferment Disease.—Robin's study of the ferment origin of cancer was mentioned in these columns recently, page 152. He tabulates here the findings from five cases of liver cancer compared with normal livers. They confirm that the total nitrogen content of the cancerous liver is less than in the normal liver. The cancer is able to construct more histologic substance out of a given quantity of nitrogen than normal tissue is able to construct from the same. The insoluble nitrogen increases, while the content in soluble nitrogen grows less and less in the cancerous tissue; the exact reverse is observed in the relatively sound parts of the liver. He interprets these and other findings as evidence that the proteic elements of the cancer are formed from the products of autolysis of the proteic substances of the organ in which it is developing. This conforms to R. A. Kocher's discovery of the increase in the hexone bases in malignant tumors. It shows the existence of a cancerizable soil, and is the direct opposite of what is observed with parasitic diseases, such as tuberculosis.

Asylums for Children with Inherited Syphilis.—Balzer describes the work of the Welander asylums in Sweden, Norway and Denmark where children with inherited syphilis are given a home and collective treatment for one, three or four years. This seems to be the only way for treatment to be kept up systematically and long enough. One great advantage of such asylums is that wettures are saved from contamination by the children. The Paris public hospital service has had to pay out from \$3,000 to \$8,000 a year to wettures contaminated by syphilitic infants. Paris has only one institution approximating the Welander asylums, and this is not restricted to syphilitic infants.

Register of Joint Excursions.—Dausset's instrument records the scope of the movements of the joint, and serves besides as a universal ergograph and machine for active mechanotherapy.

Explosions and Concussions.—Chavigny relates some experiences which seem to conflict with the conclusions neurologists have been drawing from the war cases of aerial shock. He has long made a study of the effects of big explosions, and recently has had exceptional opportunities for this as large amounts of military explosives have been exploded to get them out of the way. The officer in charge, M. Sellier, has several times set off 350 kg. of explosives in one mass at one time. He lay on the ground at a distance of only 80 meters, merely covering his head with one of the box covers to protect it against any falling stones. The explosions were so violent that they broke windows 1,000 meters away and flung open or shut doors 3 kilometers distant. But they did not produce any pathologic effect on the observer at 80 meters. He did not have the auditory sensation of a loud explosion. He felt transiently something abnormal, but the sound wave did not seem to be clearly perceived by the ear, as if the sound wave was beyond the limits of the sounds normally perceivable by the ear. Persons farther away heard the noise of the explosion as terrific. The entire lack of pathologic phenomena in these repeated experiences confirms the negative results of Chavigny's experiments on animals which showed no compression or depression from the atmospheric waves of an explosion nearby. He emphasizes the importance from the medicolegal standpoint of this lack of injury from the severe explosions. It seems to testify that most of the *commotions* have not been left with organic lesions, and hence that they need not be given the permanent disability pension. The pathologic phenomena observed thus belong in the domain of psychiatry and not in that of neurology, and hence the prognosis is generally so much the more favorable.

Pneumococcus Antiserum.—Truche relates that for years he has made a special study of serotherapy of pneumococcus infections and declares that the unmistakable benefit from it

is now established beyond question. In pneumonia, deferrescence follows in one or two days and the pulse drops to 80 on an average. In pleurisy the serotherapy effectually supplements surgical measures. In mixed meningococcus and pneumococcus meningitis the antisera for each should be used. Blacks are very sensitive to pneumonia, but under this serotherapy Blazy found the death rate drop from 32 to 12 per cent. and Lassance, from 13 to 7 per cent. Truche immunizes the horses with very virulent pneumococci, killed with ether and alcohol, and diluted with large amounts of tepid physiologic fluid. He tests on mice the antiserum thus derived.

*Cancerous Limits of Stomach in Scleritis. P. Carnot.—p. 576.

*Malaria and Typhoid. E. Job and L. Hirtzmann.—p. 581.

Pathogenesis of Malarial Attacks.—Abrami and Senevet explain that the malarial attack is the consequence of an anaphylactic shock from the sudden passage into the blood of a heterogeneous colloidal substance, from the bursting of large numbers of rosettes at one time. Their tests demonstrate that the blood may not show a single merozoite four hours before the ague chill, but an hour later there may be 450 per cubic millimeter. This testifies to the bursting of large numbers of rosettes, and the "crisis of hemoclasia" is then under way and reaches its height in two or three hours with the chill. This analogy between the ague chill and the anaphylactic shock suggests the possibility of warding it off by anti-anaphylaxis methods. It also explains some of the satellite symptoms of the ague chill. The algid phase is one of the most constant symptoms of the hemoclastic shock, and prompt intravenous injection of 1,000 mg. of physiologic serum containing 2 mg. of epinephrin has revived the patients at once in their experience. In two of their cases the apparent signs of death had been noted for five minutes when resuscitation followed this injection, supplemented by artificial respiration. Both these patients are now in perfect health. If the algid phase had been the result of insufficiency of the suprarenals, this could not have been remedied by this injection which, however, safely tided the patients past the danger point of the hemoclastic shock.

The assumption that the ague chill and fever are only the tardy consequence of the anaphylactic (hemolysis or hemoclasia) shock, brings the logical conclusion that it might be aborted by the preliminary injection of a small amount according to the Besredka method. They selected as the substance to be injected the patient's own serum, injecting 20 c.c. eight hours before the expected attack. They thus treated six patients who were having daily malaria attacks and who had not been treated otherwise. In three the injection had been made an hour or two too soon, but in the others the attacks were essentially attenuated or there was no chill or sweating. These effects were so marked under the circumstances that they demand further trials on a larger scale. Peptone given every two or three hours before the attacks might likewise ward it off as it wards off urticaria and migraine in certain cases. Although this would have no influence on the proliferation of the parasites, it might prevent the physical process of the sudden upset in the physical balance of the blood plasma. The fever is the manifestation of the upset in the blood, and the parasite does not induce the fever so much by its toxins as by its hemoclastic, heterogeneous colloidal body. This is probably not peculiar to malaria. Systematic study of the blood might show other diseases a similar premonitory blood crisis.

Hexamethylenamin in Typhus.—Glataud reports a decided reduction of the temperature in six cases of typhus in which

he had given a daily intravenous injection of hexamethylen-amin. The dose was 1.5 gm. in 5 c.c. of vehicle. No more than four doses were given in any case. The temperature began to go down after the first dose; the charts show the same drop by lysis in the three cases in which the drug was given early. A similar effect was observed in influenza, but it was not so prompt or so decided as in typhus.

Alimentary Antianaphylaxis.—A report of similar experiences by these writers was summarized, May 24, 1919, page 1577. Shellfish, lobsters, and condiments in the cases related seem to have been responsible for the urticaria and Quirk's edema. A complete permanent cure seems to have been realized by the preliminary injections of peptone.

Measurement of the Spleen.—Chauffard draws a line from the middle of the axilla to the trochanter region, the arm held above the head. This line serves as the base from which the ovoid spleen is palpated and percussed, and the outline marked also on the skin. A line is then drawn from the base line, axially, to the farther limit, forward, of the spleen. This axial line is bisected in the center by a line perpendicular to it. We thus have two lines that can be measured and compared from case to case, giving thus the approximate size of the spleen.

Alimentary Anaphylaxis.—Johrain reports three cases in which the antianaphylaxis treatment proved effectual. Two of the patients were children who developed urticaria after eating eggs, or certain other food. The third was a young man with attacks of asthma nearly every evening, three or four hours after eating. All seemed to be cured completely by taking 0.5 gm. of peptone half an hour before breakfast and dinner for twenty days, with certain dietetic restrictions.

Cryptogenous Fevers.—Léopold-Lévi reports the details of three cases in children in which no cause could be found for the slight but tenacious fever. The thyroid seemed to be in an unstable condition, signs of deficient and of excessive thyroid functioning appearing irregularly. One of the children was physically and mentally inclined to myxedema mornings and to Basedow's disease evenings. The unstable temperature flared up and died down. The benefit from thyroid treatment in these cases confirms the assumption that the unstable thyroid was the main factor in the disturbances. Until thyroid treatment thus proved its efficacy, latent tuberculosis, chronic appendicitis, etc., had been suspected.

Serodiagnosis of Syphilis.—Bénard and Pinard extol the advantages of using fresh serum for the Wassermann reaction and tell of their experience with it in 224 cases. They found this technique (Hallion and Bauer, 1912) simpler, earlier and more sensitive than others.

Dysenteriform Spirochetosis.—Delamaré found refracting spirochetes in twenty of 142 specimens of pathologic stools examined. These spirochetes resembled so closely those of bronchial spirochetosis that they seemed to be identical. In treatment, arsphenamin or emetin (in cases of associated amebiasis) proved effectual.

Malaria and Typhoid. If the malaria developing during typhoid or paratyphoid is recognized and gets proper treatment, the prognosis is benign except as the typhoid is aggravated. Paratyphoid bacilli may be found in the blood during malaria although sometimes apparently doing no harm.

Wounds of the Chest. A. Schwartz, p. 485.

Rectal Polyposis. P. Carnot, Friedel and Froussard, p. 495.

Wounds of the Chest. Malaria Parasites. F. Dubois, p. 497.

Wounds of the Chest. This is a ten page general review of the subject from the clinical and therapeutic standpoints.

Rectosigmoid Polyposis. Carnot, Friedel and Froussard report a case of generalized polyposis of the terminal bowel in which a cure was realized under local applications.

Wounds of the Chest (Gibrous de moutons). The farmer, Chéreau, 36, had long had chronic ulcerative rectosigmoiditis, the base of which innumerable small polyps had developed. The inflammation was so intense that the lumen of the

rectum no longer admitted the finger. The rectosigmoid segment was dressed every day, after a cleansing enema, with a thick agar mucilage containing at first 10 gm. of magnesium chloride and later 5 gm. in about 250 gm. of this vehicle. The mucilage was introduced above the stenosis, using a sound and Guyon syringe. This local dressing was borne easily and retained longer each time, two, six, ten hours. The 5 gm. strength is borne well; the stronger solution was expelled too soon. Rectoscopy in less than three weeks showed that the ulcerations had healed, and in the following two or three months the polyps were gradually absorbed until there are now only a few minute polyps that have not been absorbed, and the general health is excellent. The rectosigmoid segment of the bowel is subject to antiperistalsis if the desire to empty the bowel is resisted. They confirmed this with roentgenoscopy in several other patients. Hence the local dressing injected is carried up and spread around. It may be forced back as far as the cecum. A mucilaginous vehicle with emetin may prove useful in local treatment of amebic dysentery in the same way.

The Crescents of Malignant Tertian Malaria.—Deglos noted that all the cases of malignant malaria developed during warm weather, and that during the cold months the parasites already in the blood left the periphery and installed themselves in the spleen. Here they were able to resist treatment until a combination of quinin, arsenic and methylene blue routed them out and cured the patients. Experimental research on the action of cold on these parasites confirmed their apparent inability to stand cold.

*Retention of Chlorids and Urea in Nephritis in Children. P. Nobécourt, p. 341.

*Regeneration of Bone. D. de Frenelle, p. 342.

Retention of Urea and Chlorids with Nephritis in Children.—Summarized, July 19, 1919, page 230.

Regeneration of Bone.—De Frenelle has watched the healing process in a number of war wounds in which the bone was widely exposed. He saw that when there was a bridge of bone between the two fragments of the long bone, the new forming bone issues from the marrow canal of each fragment, and lines up on the lower surface of the bone bridge, working toward the center of the bridge where the two ends finally meet. The wider the bridge surface facing the marrow canal, the wider the growth of new bone tissue creeping along it from the end. The new forming bone tissue works its way into the bone bridge better the more spongy its texture. As this proceeds, the bone bridge becomes spongier, the holes larger, the new forming bone tissue evidently appropriating to itself the calcium salts in the bone bridge. These observations teach the necessity for opening up the marrow canal into sound tissue, from which the new forming bone tissue can sprout. In implanting a bone graft to serve as the bridge, space must be left on the under side for the new forming bone to creep along it. The implant should be of spongy bone and should be strong, the strength depending more on its width than on its thickness. The wider it is, the larger the expanse of regenerating bone that will line it. If too thick, it will hamper the regeneration of the bone by connective tissue-vascular regeneration; this occurs at the sides of the bone bridge, or on top, from scraps of bone and periosteum debris left from the traumatism.

The bone bridge is finally absorbed until nothing is left but a thin shell over the thick mass of new formed tissue which unites the fragments of the bone. The tissues that surround the implant have little to do with the regeneration of bone, and hence it is not necessary to freshen them; but the ends of the implant and of the bone fragments must be carefully freshened. It seems to be immaterial whether the graft is accompanied with its periosteum or not. The advantage of keeping the periosteum is apparent only when the implant gets broken in grafting it. It is not necessary to mortise the bone graft in place. Pointing the ends of the implant and sticking them into the marrow cavity of the stumps holds it firm, but to reinforce it a metal cuff is fitted

to each stump with a narrow but strong metal bridge between them which serves to immobilize and protect the bone implant without touching it.

*Natural Carbonated Baths in Treatment of High Blood Pressure. C. de la Carrière.—p. 349.

*Roentgen Findings with False Pneumothorax. H. Lebon.—p. 351.

*War Psychiatry. R. Benon.—p. 352.

*Integral Segregation of Urine. Gudin (Rio de Janeiro).—p. 354.

Carbonated Baths in Treatment of High Blood Pressure.—The natural carbonated baths at Royat are said to have a general modifying and tonic action on the nutrition and diuresis. They also dilate the peripheral vessels and thus aid in lowering the blood pressure, while they tone up the heart.

False Pneumothorax.—Lebon's roentgenograms illustrate the decisive differential importance of roentgen examination in cases of supposed pneumothorax. Three typical cases are described. In one the stomach was distended with gases and projected far into the left side of the thorax, pushing the heart over toward the right. In the second case the air bubble in the stomach lay between the left margin of the heart and the wall of the chest. In the third case the stomach was greatly distended with gases and projected high in the left thorax; the roentgen picture was crossed with three large shadow stripes, all starting from the lower right corner.

War Psychiatry.—Benon exclaims that etiology is a thankless science, and analysis of the causes of war nervous affections is peculiarly difficult. One factor he thinks has not been given full credit. This factor is physical overexertion. It entails a condition of nervous exhaustion, general asthenia, and this may entail various psychoses, hypochondria, melancholia, ideas of persecution or dementia praecox. When the asthenia has subsided, or if it has given way to mania or hypersthenia, various forms of intermittent psychoses may develop.

Segregation of the Urine.—Gudin remarks that the ordinary ureter catheter allows urine to flow down along its sides, so that actual segregation of the urine from each kidney is impossible. He remedies this by having the catheter tip made with a pointed olive. This is easily worked into the ureter mouth, and there the olive plugs the lumen of the ureter completely so that no fluid can escape outside of it. He gives illustrations of the cystoscope containing the two olive-tipped catheters. He introduces the catheters into the bladder first, and then slips the outer ends into the cystoscope which is then pushed up into the bladder, guided by the two catheters. The olive tips are too large to enter the lumen of the cystoscope, so the catheters are worked backward into the cystoscope as the latter is introduced. It is then a simple matter to introduce the olive into the ureter; it does not have to be pushed in far to collect all the urine from that kidney. He uses a cystoscope in which the light and the opening for the ureter catheter tips just below are on the opposite side from the curve of the tip. He has been applying this method for three years and with constant success.

*Spinal Anesthesia. H. P. Achard.—p. 239.

*Spa Treatment of Vascular Affections and Hypertension. A. Mongeot.—p. 240.

*Secondary Sarcomatous Polyposis. L. Thévenot and Bouget.—p. 242.

*Iodine Vapors in Ear, Nose and Throat Disease. A. Maurice.—p. 244.

Spinal Anesthesia.—Achard states that he has applied staviam low rachianesthesia in 123 cases and procain anesthesia in 290—thus well over the 400 mark. There were no fatal accidents and no durable injury in any case, but some disturbances developed within an hour or during the three following days in a few. Analysis of these cases demonstrates, he says, that the only failures were due to defective technique, and with greater experience they grew less frequent. The only mishaps were transient headache indicating slight irritation of the meninges. This was noted in 10 per cent. of the procain cases and in 50 per cent. of the staviam cases. The few cases in which an English make of procain was

used all developed headache or pain in the spine; in two cases the latter kept up for five days. Postoperative vomiting and nausea for a few minutes were noted in 10 per cent. of all the cases, and a tendency to brief syncope was evident in 4 per cent. of the procain and in 10 per cent. of the staviam cases. Incontinence of the sphincters is annoying. It occurred in 50 per cent. of staviam cases but less frequent with the procain. The operations were all below the umbilicus and no attempt was made to have high anesthesia.

Sarcomatous Polyposis.—In Thévenot's case and in one reported from Athens the sarcomatous polyposis of the small intestine was secondary to a sarcoma in the mediastinum or rectum. In both the polyposis induced invagination.

Nascent Iodine in Treatment of Ear, Nose and Throat Disease.—Maurice has applied *enfumage iodé* by heating iodoform and insufflating the vapors directly to the focus in tonsil, nose, maxillary sinus or middle ear. In chronic otitis media it has proved a potent adjuvant to the usual measures. It often heals suppuration in the ear without the necessity for destructive operations. He warns that not more than two or three jets should be insufflated at one sitting, as more than this may cause painful distention.

*Hydrannios after Death of Fetus. P. Balard.—p. 187.

*Gynecologic Treatment of Retrodisplacement of the Uterus. H. Sosnowska.—p. 191.

Pituitary Treatment in Gynecology.—Dalché gives pituitary by the mouth, preferring the dry extract of the whole gland, giving from two to four cachets a day of 0.10 gm. each. This treatment can be applied in every case of metrorrhagia, and it often will give good results. But success depends on its being kept up perseveringly for weeks and months with bleeding fibromas, diffuse fibromatosis and sclerosis of the uterus, retrodisplacement with congestion, vaginal metrorrhagia, intermenstrual dysmenorrhea—whenever, in short, the aim is to modify a condition of long standing. For example, a young girl with too frequent and too profuse menstruation should take the pituitary extract every day for a month, then for two weeks each month, beginning the week before the anticipated menses and continuing till the close. The other two weeks he orders 10 drops of tincture of hamamelis in a little water before the two principal meals. In case of a fibroma he alternates the two pituitary weeks with other organotherapy, and may conclude with roentgen treatment. Congestions and excessive functioning of the ovaries or thyroid may likewise benefit by pituitary treatment, as also certain types of headache, even those suggesting false brain tumors, with exacerbations at the menstrual periods. It seems in these cases as if the endocrine upset had indeed congestion in the pituitary body and that this congestion was what causes the headache. The action of pituitary treatment is not restricted to the genital organs; it may attenuate and suppress the hot flashes and sudden sweats of the menopause and other symptoms of ovarian insufficiency. It seems to promote sleep, appetite and diuresis, and combat asthenia.

Hydrannios Increases After Death of Fetus.—Balard reports the case of a woman who had had puerperal endometritis, and the fetus died at a following pregnancy, not long before term, but the hydrannios grew larger and larger thereafter. Three liters of fluid at least flowed from the uterus after delivery of the child. The uterus had kept on rapidly increasing in size after the fetus had died. This does not harmonize with the current views in regard to the causation of hydrannios.

Gynecologic Treatment of Retrodisplacement of the Uterus.—Sosnowska discusses how best to reduce the congestion in the pelvis, and also tone up the round ligaments with muscular exercise so they will regain their elasticity and pull the uterus up into place. The resorption of adhesions must also be promoted. The diagnosis of retrodisplacement is not

always easy; the symptoms may suggest tubal pregnancy, a hematoma in an ovary, a suppurating salpingitis or small dermoid cyst. These excluded, gymnastic exercises and massage may restore tone to the muscles, and the displacement then will correct itself. Brandt advocates "pelvic manotherapy" by introducing thumb and forefinger into the vagina and rectum and manipulating the uterus between them, the patient standing. Or with the finger in the vagina and the other hand on the abdomen the uterus is worked up into its normal position, the patient reclining. These different maneuvers are shown in five illustrations. The pelvis is exercised by three movements done by the patient as she lies on her back with knees spread apart: lifting the buttocks above the plane of the bed, contracting the levator ani muscles as if to retain a large enema, and at the same time pressing the knees together against resistance. The patient must be trained to do these exercises separately and then together, morning and evening. The bowels must be kept open; out of door life, deep breathing, sun baths, etc., aid in the general restoration of vigor and tone, as retroversion is usually the result of general ptosis or relaxation of the ligaments stretched by a pregnancy. The above treatment is particularly effectual with intermittent deviation from congestion in the pelvis, usually traceable to chronic intestinal stasis.

Gallop Rhythm in Children.—Morquio declares that the sounds with gallop rhythm have a different significance in children and in adults. In adults it is an evidence of interstitial nephritis and arteriosclerosis, of which the most characteristic manifestation is the overhigh blood pressure. In children, both arteriosclerosis and interstitial nephritis are exceptional. He has met only one case in a child of interstitial nephritis like that in adults; it followed infectious purpura. Gallop rhythm in children is a sign of weakness of the heart, or of toxic action on its muscle or innervation, or of inflammatory or degenerative processes in the myocardium. Consequently we encounter gallop rhythm in a number of different diseases entailing these conditions, such as acute nephritis, heart disease, and in typhoid. He describes in detail some cases of different types. In one a girl of 9 with diphtheric polyneuritis and paralysis showed pronounced gallop rhythm for a few days, but then it disappeared as the child slowly recovered. The heart findings were normal when she was discharged from the hospital. Antitoxin had been given freely to combat the evident nephritis, notwithstanding the gallop rhythm and that antitoxin had been given during the primary diphtheria. It had evidently not been given in sufficient amounts then. Another child of 4 presented intense gallop rhythm as almost the only manifestation of an acute nephritis. It disappeared in a week under repose and restriction to a milk diet, flushing the intestine well every day.

Diphtheria antitoxin has never caused any injury in the numerous cases in which he has given it when there was nephritis. It benefited not only the causal diphtheria but the nephritis as well. In one case of severe diphtheria the anasarca and intense albuminuria had withheld the physician from giving antitoxin freely, but after the child was given large doses of antitoxin after intubation, the child's condition began to improve at once. Nothing contraindicates antitoxin in a case of diphtheria. Another case is described in which the precordial gallop sounds were due to the grave toxic condition in severe typhoid fever. The gallop rhythm denoted myocarditis which assumption was confirmed a week later by necropsy. Myocarditis is a rather frequent complication of typhoid in children; he has encountered it in from 5 to 6 per cent. of his cases of typhoid in children, not always in the graver cases. It generally comes on by the end of the second or third week. In this case it enabled the myocarditis to be recognized from the first and warned of the peculiar gravity of the case, although typhoid myocarditis as a rule is less severe in children than in adults. Calamet has compiled twelve cases with a favorable outcome in a total of twenty-four cases.

Children who have had the myocardium seriously touched by the infectious process should be kept under supervision. It may explain sudden death not long after, or acute asystole, etc., in children after special physical exertion, or the myocarditis in childhood may be the basis of heart disease in the adult. The details of another case are given in which the cardiopathy with the gallop rhythm was the result of acute rheumatism; even if the child had survived the acute stage, he would have suffered from adherent pericarditis. Morquio deplors that some physicians regard rheumatism in a child as comparatively unimportant, and do not give the salicylates in adequate dosage to ward off invasion of the heart. He reiterates that sodium salicylate given in time and in proper doses will almost invariably ward off the participation of the heart. When there is persisting gallop rhythm with rheumatism myocarditis, along with other signs of cardiac insufficiency, the assumption is justified of grave changes in the heart muscle. It may be encountered also, without being constant, in the exacerbations of chronic conditions. With acute nephritis, mere dilatation of the heart may bring on gallop rhythm, but the whole is transient. The process is graver with rheumatism heart disease, although it may subside with the other functional disturbances. The prognosis is graver in typhoid fever and in severe toxic-infectious conditions in which the gallop rhythm is a sign of severe myocarditis.

Otitis Media.—Gianetto and Martino describe with sixteen illustrations the various ways in which an inflammatory

process in the middle ear may become walled in, and how it may require a specially localized paracentesis.

Peritonitis from Typhoid Perforation.—Devincenzi comments on the unprecedented frequency of cases with perforation of the bowel during the last epidemic of typhoid. It occurred in 14.4 per cent. of the eighty-four cases in men at the Maciel Hospital, while he has been unable to find on record any such high percentage. The range in 23,113 cases he has compiled from international sources was from 1.75 to 6.54, with an average of 3.73 per cent. The women in his hospital seemed to escape, there being only 3.33 per cent. among the sixty women. He discusses the symptoms, pathologic anatomy and treatment. With prompt operation, 27 per cent. were cured in the cases he has compiled and 38.46 per cent. in his own service. He describes the technique he prefers, isolating the injured loop, with a double plastic reinforcing of the less gravely affected tissues. The operative cases are reported in detail.

Cystoscopy.—Carve expatiates on the advantages of the double catheter cystoscope. He uses a No. 23 or 24 Charrière which allows the introduction of two No. 16 Peacock catheters so that both ureters can be catheterized at one examination. The cystoscope also enables meatotomy of the ureter to be done with precision and without danger. It also facilitates intravesical electrocoagulation procedures. It can be used for dilating the ureter and draining the kidney without special apparatus or catheters. It may also ward off disturbance from local accumulation of blood with intense renal hematuria, and, finally, it may confirm the diagnosis of a bifid ureter. He describes each of these special applications, giving instructive instances.

There had been no physical effort, and the only explanation possible seemed to be the prolonged weeping.

Gaceta Médica de Caracas, Venezuela

May 31, 1919, 26, No. 10

Chagas' Disease in Venezuela. E. Tejera G.—p. 103.

American Trypanosomiasis.—Tejera presents conclusive evidence that the trypanosome thyroditis described by Chagas in 1907 as common in children in certain parts of Brazil prevails also in Venezuela. He reports two cases, in an infant and a boy of 2, belonging to the states of Trujillo and Zulia. His extensive study of the subject has demonstrated further that it is transmitted by a different insect from the one responsible for it in Brazil, *Lamprophya* (*Conorhina*) *megistus*, as this does not seem to occur in Venezuela. The bug responsible for the transmission in Venezuela is *Rhodnius prolixus* Stål, as he determined by extensive experimental research and these clinical experiences. These insects in nature may harbor *Trypanosoma cruzi*. The insects are called by various names, pite, chupón, quipito, chinche de monte and chips. It is a night-biting insect of the reduviidae family. Some specimens sent to Paris in 1913 from Venezuela were artificially infected by feeding them with *Trypanosoma cruzi* sent from Itaboraí, Brazil. Ruemees presented Tejera's report from the laboratory of the Caribbean Petroleum Company at Mene Grande, and he added that a few years ago he urged research in Venezuela to find whether this American trypanosomiasis was restricted to Brazil alone. Tejera mentions in conclusion that as goiter seems to be endemic in the Santander district in Colombia,

Chagas' disease probably could be discovered there also. He was examining the rhodnius for leishman bodies, in a study of the discovery in them of *Trypanosoma cruzi* of Chagas' disease. But his clinical cases of the latter came from a different district, and he found the trypanosome likewise in specimens of rhodnius from the environment of the patients. Rats, cats, monkeys and other animals inoculated from the insects developed the trypanosomes in large numbers in the blood. Ayala added that Tejera's research seems to exculpate the drinking water in respect to endemic goiter. He appealed further for research to decide whether there may not be some plant which serves as a host for the trypanosome like the euphorbia for the leptomonas (Iturbide), suggesting some zoological affinity between plants, leishman bodies and trypanosomes.

Parenteral Injection of Milk. B. C. Durán.—p. 162. Cont'n.
Premature Separation of Normal Placenta. Apalodo.—p. 164.

Rachitis and Digestive Disturbance.—Pereda insists that the bone anomaly in rachitis is not due principally to the deficiency in calcium, as infants fed on breast milk but not getting enough do not show any signs of rachitis or spasmophilia. Cow's milk, although it contains more calcium, breeds rachitis; not human milk. Cow's milk produces putrefaction in the intestine, and the toxic substances thus generated are responsible for the rachitis. Treatment of rachitis should therefore aim to restore normal conditions in the digestive tract, after which the bone conditions will right themselves, he declares, as the infant gains in weight.

Cholera, Typhoid, Fruit and Vegetables.—Murillo found typhoid bacilli still active and virulent from thirty to thirty-six days after they had been incorporated with garden dirt, or after low growing fruits and vegetables had been sprayed with them. In sterile sand they lived at least fifty-five days. These facts suggest that salads and raw fruits and vegetables of different kinds are a considerable factor in typhoid in Spain. His experiments with cholera germs were equally conclusive up to three weeks in soil contamination and two weeks in irrigation.

Emetin in Hemoptysis.—Blasco reports that he has succeeded in arresting the tendency to hemoptysis with emetin when all else had failed, and he regards it as a most powerful aid in combating hemoptysis in pulmonary tuberculosis. He injected subcutaneously 0.04 gm. of emetin hydrochlorid in 1 c.c. of vehicle. It never caused pain or inflammation, even when three doses were injected in twenty-four hours, to a total of 0.12 gm. The tendency to hemoptysis seemed to be arrested in from one to three hours except in the cases with fever and in the subacute forms of pulmonary tuberculosis. With these, emetin does not display any influence. Its therapeutic action is due to its effect on the smooth muscle fibers, and especially on the bronchopulmonary vessels. It should not be given to pregnant women on account of the danger of abortion, and old, inactive specimens of emetin should never be used.

Puerperal Eclampsia.—Calvo remarks that women are too apt to bear in silence and ascribe to the pregnancy alone certain symptoms which should warn of impending trouble.

Especially during the last month, headache, epistaxis, pain in the kidney region and high arterial pressure should cause the physician to be sent for at once. In a case described in a young primipara this was not done until eclamptic convulsions had developed. The pulse was hard and fast. On exploring the abdomen, the uterus contracted and this brought on another convulsion. As delivery was impending, he completed manually the dilatation of the cervix, already as large as his palm, and delivered an unusually large child. As the placenta came away there was much hemorrhage from inertia of the uterus, but it subsided under pituitary extract. The convulsions then returned every half hour, twenty-four in all, until he injected morphin and gave chloral by the rectum. After this there were no further convulsions but the woman lay unconscious for forty-eight hours, the organic functions, urine, lochia and stools, suppressed. Then the temperature ran up high and he gave 500 gm. of sugar solution and an embrocation of aromatic vinegar with a hot pack, and drew the urine. It was small in amount, very turbid and fetid, with 1.7 per cent. sediment, half of which was made up of streptococci and colon bacilli. The serotherapy and aromatic vinegar were applied again as the temperature ran up anew to 104 F. The urine was drawn every two hours and the vagina was douches with boiled water, and water was given by rectum. The woman gradually recovered, the urine still testifying for some time to suppurative in the urinary passages until recovery finally seemed complete.

*Euphthalmic Goiter. A. Rocha G.—p. 468.

*Indications for Arphenazin in Syphilis. M. A. Rueda G.—p. 472.

Deafmutism.—Fajardo Vega discusses deafmutism from the standpoint of legal responsibility, querying whether the deafmute's being shut off from the conventional training does not preclude his having a proper conception of abstract ideas of right and wrong. In his expert testimony in a concrete case described, he declared that deafmutism does not compromise the mind, and deafmutism should not be classed with dementias as is done by the Code now in vogue in Colombia, the words *dementia* and *sordomudez* being used as if synonymous.

Euphthalmic Goiter.—Rocha's patient, a woman of 65, presented the complete picture of the disease according to the classic descriptions. After marked improvement under direct thyroid treatment for a time, the symptoms began to grow worse. Then followed great and persisting improvement under treatment with the blood from a goat thyroidectomized for the purpose. This treatment had to be suspended at the fifth month, and the symptoms reappeared but were transiently benefited by thyroid treatment again. The thyroid still showed alternating phases of excessive and deficient functioning.

*Delirium as of Psychos. J. M. Jorge, Jr.—p. 243.

*Improvement in Psychoses after Operations. G. Madero.—p. 76.

Epinephrin in Heart Block.—Arrillaga gives twenty-nine electrocardiograms from six patients with more or less complete interruption of the muscular connection between the auricle and ventricle. The cardiograms mirror the effect of epinephrin under these conditions. The auricle and ventricle react to the epinephrin parallel and simultaneously as a rule, but occasionally the ventricle responds first. The epinephrin accelerates the contractions, and the effect is more pronounced the greater the deficiency in suprarenal functioning. The epinephrin was always injected subcutaneously, 0.001 gm., and cardiograms were taken at intervals up to an hour and a half afterward. In one man of 55 with a ventricle beat of 30 and an auricle beat of 93, the latter increased to 159 while the auricle beat ran up to 129, but the normal rhythm was

never restored in any of the tests in any of his cases. Even when the rhythm seems normal to the finger, the electrocardiogram will show the anomalies. He adds that epinephrin constitutes *toda una medicación* in heart block, and that it should not be forgotten in transient heart block from the use of drugs or effect of toxins.

Benzol in Treatment of Uterine Cancer.—Bordarampé had a case of epithelioma of the uterine cervix which was inoperable and progressing and radiotherapy was not available at that time. As a last resort, he applied a tampon wet with pure benzol directly to the neoplasm, leaving it in contact for five minutes and then replacing it with a dry tampon. Besides this, two douches were given daily, each with 2 liters of hot boiled water containing each 50 drops of benzol. The fluid was stirred while the douche was being given. Under this treatment the neoplasm shrank and healed over, and in four months the woman increased 10 or 12 kg. in weight and felt very well. The cancer healed until its operative removal was justified. In a second, similar case the cancer shriveled to a very small bunch under six months of treatment. Then it began to ulcerate again, its aspect then suggesting a superposed syphilitic lesion as the Wassermann reaction was positive. Arsenic and mercury were then given, but under this treatment the cancer flared up anew and metastases developed at various points. Seven other patients have been treated since, with permanent success so far as known. Two are still under treatment; one is progressing well but the other has hemorrhages, and no measures seem able to arrest this tendency to hemorrhage.

Tuberculosis of the Pubis.—Jorge gives the details with illustrations of a case of symmetrical tuberculous fistulas in the pubis as the only appreciable manifestation of the disease. The patient was a little girl of 8, weighing 21 kg. The fistulas healed at a seashore sanatorium and the child weighed 35 kg. when sent home definitely cured. Jorge has been able to find on record only sixty cases of tuberculous lesions in the pubis, and the case histories are incomplete in many of these. As a rule the lesion was the only manifestation of the disease except when it was merely an extension of tuberculous hip joint disease. The pain usually is not severe, and it comes on after exercise, but extremely painful points can be discovered in the pubis. Even after apparently complete cure, the focus may flare up again many years later, especially after a pregnancy, or without apparent motive in strong and robust men. In his case the abscesses kept suppurating after six months of general treatment, heliotherapy, etc., and three months of Beck's paste or other local measures. Then he curetted the fistulas and the foci in the bone, and this started the process of local repair. Radiography soon showed that healing was complete. There does not seem to be any need for resection of the pubis, as ample curetting apparently answers every purpose.

Surgical Affections and Psychoses.—Madero reports three cases in which an operation for appendicitis, for an abscess in the thigh or stones in the bladder was followed by the subsidence of the tendency to delirium and melancholia. The surgical affection in each case was a chronic infectious process with acute exacerbations and much pain. These psychoses of infectious origin are entirely distinct from the delirium of a true infection which subsides with the infectious disease. The "peripheral delirium" may outlast the peripheral lesion, and may keep up until the general health improves after the disease focus has been eradicated. The patient with this kind of a psychosis, he remarks, is a "hypochondriac interpreter of organic mischief."

*Vaccination against Anthrax. R. Kraus and P. Beltrami.—p. 98.

*Epizootic among Horses. R. Kraus, G. Fischer, and L. Kantor.—p. 114.

Nonspecific Treatment of Anaphylaxis and Allergy.—Kraus describes what is known to date in regard to active and passive anaphylaxis and specific and nonspecific treatment. With his co-workers at the Hospital Múñiz he noted that normal beef serum used in treatment of anthrax caused serum sickness in only 2.1 per cent. of 290 patients treated with it. They proceeded to make a bovine antiserum for both diphtheria and tetanus, using cattle instead of horses for production of the antiserum. This bovine antiserum is not so potent as horse antiserum, but serum sickness was very rare with it, even when large quantities were injected to bring the amount of units up to the required figure. Serum sickness was also very rare when the antiserum from both sources was injected together or, better yet, first the bovine and then the horse antiserum. When the horse antiserum was injected first, 27.2 per cent. of the thirty-three diphtheria patients developed urticaria and 18.1 per cent. serum sickness. Only 3.1 per cent. developed serum sickness among ninety diphtheria patients treated with the bovine antiserum alone. Kraus refers further to the attenuation of scarlet fever in children previously injected with horse diphtheria antitoxin, as reported by Benjamin and Witzinger, and the benefit from normal beef serum in hay-fever. Heterobacteriotherapy and protein therapy and the modification of certain pathologic processes under the influence of intercurrent infection, in connection with the above, all suggest that we are entering on an era of anti-allergy therapy as the logical next step from antitoxin therapy.

Typhus.—Kraus relates the history of typhus in America from its first recorded epidemic appearance early in the sixteenth century, when 200,000 persons died from it in Peru. In South and Central America, Mexico and India, typhus seems to be restricted to mountainous regions and is rarely encountered on the coast. Battaglia and Barla report their experiences in stamping out an epidemic of typhus in Argentina.

Vaccine Therapy of Influenza.—Kraus and Kantor found the influenza bacillus in 60 per cent. of sixty cases but always associated with the pneumococcus, streptococcus and parameingococcus. In 36.6 per cent. only these were found. They prepared a vaccine with all these bacteria from the patients, treating the bacteria with ether and injecting subcutaneously a dose of 1,000 millions once or twice. Among 204 healthy persons vaccinated none developed serious influenza, and only 1.47 per cent. developed the disease in a mild form, and this within four days of the vaccination, before it had had a chance to actually immunize. The ages ranged

from 15 to 30, and the vaccination was done when the epidemic was at its height. Among ninety-eight unvaccinated at the institute, 65.3 per cent. developed the disease.

Influenza Bacillus in the Air.—Negrette was able to cultivate the influenza bacillus from the air of wards containing influenza patients, but never from the air of other wards.

Vaccine Against Anthrax in Cattle.—Kraus and Beltrami urge the necessity of state control of this vaccine, and of international standards, as well as study of the doses, the immunity, its duration, etc. They urge the appointment of an international commission for this purpose.

The Prevailing Disease Among Horses.—The research reported by Kraus, Fischer and Kantor confirms that the prevailing epizootic is the typical meningo-encephalitis described by Borna.

*Vasomotor and Trophic Disturbances in Hysteria. E. Macris.—p. 13.

*Breaking Down of the Foot. J. G. Chrysospathis.—p. 15.

*Cycloma of the Solar Plexus. G. Dré Kolias.—p. 17.

Trophic Disturbances in Hysteria.—Macris reports the case of a hysteric young woman who each time after three sittings of hypnosis had what seemed to be nightmares in which she screamed that she was being burned, and patches of erythema developed, with phlyctenae by the next day. She was a maid in a physician's family, and the supervision of the second and third attacks apparently excluded deception and stamped the phenomena as auto-suggestion in a dream.

"Forced Foot."—Chrysospathis reports the case of a healthy soldier of 35 who after a very long and fatiguing march felt suddenly intense pain in the right foot, without trauma to explain it. One of the metatarsal bones had fractured. He ascribes this to the exhausted condition of the muscle which relaxes and allows the heads of the metatarsal bones to hit the ground. This fracture may result from this extreme fatigue and forcing of the foot. Besides soldiers, waiters, housekeepers and others who have to stand long on their feet are liable to develop similar disturbance, and it may return.

Disturbances from Anomalies in the Solar Plexus.—Dré Kolias ascribes to reflex action from irritation of the solar plexus a number of disturbances in the pneumogastric-sympathetic system, including hiccup, abdominal painful points, reflex disturbances in the throat, sweat glands, heart and pupils, as well as certain functional brain and spinal cord disturbances. He describes in detail a striking case in a young woman who for three years had been having pains in the stomach region and, later, also girdle pains below, various tender points in different parts of the abdomen, pains in the temples and back of the neck, with occasional loss of consciousness and vomiting. She was sent to the hospital with the diagnosis of recurring hematemesis from gastric ulcer plus hysteria. The abdomen was distended, painful at different points, especially over the adnexa, and there was a hemorrhagic gingivitis. Dré Kolias was convinced that the solar plexus was responsible for the larger part of the symptoms, and instead of operating on the stomach he opened up the solar plexus and dissected around the tripod formed by the celiac trunk, breaking the filaments of the solar plexus to detach the semilunar ganglia. The operation relieved the young woman of all pains and the "hysteric ball," and when last seen nine months afterward she was in florid health. Jaboulay published a case of the kind treated

in the same way by what he called *elongation du plexus solaire*. Dr. Kolias calls the clinical picture *cyclome du plexus solaire*, and declares that his success justifies wider application of operative relief for functional disorder from the solar plexus.

Mededeel. Gen. Laboratorium te Weltevreden, Java

1919, No. 1, 3, Parallel Dutch-English Edition

Fat and Lipoid Content of Blood in the Tropics. F. and E. Wechunen and C. Alting.—p. 29; C. D. de Langen and H. Schut.—p. 44.
Dysenteric Bacilli. W. J. L. Duke.—p. 68

Fat and Lipoid Content of the Blood in the Tropics.—There seem to be some sources of error with Bang's micro-method for determining different elements in the blood, and the research here described was undertaken to eliminate these. The methods and findings are described in detail. De Langen and Schut describe clinical experiences, all testifying to the importance of chemical examination of the blood as throwing light on metabolism. Especially in beriberi, the lipid content of the blood seems to be connected with the disease. Hookworm induces a peculiar orange yellowish tint of the skin, showing that in this disease likewise the apochrome content of the blood is abnormally high. The fat content of the blood is exceptionally low with beriberi, and they have noticed that persons with hookworm usually escape beriberi. In the seven cases of beriberi examined, the fat content of the blood was exceptionally low, some patients presenting less than a third of the normal figure.

Dysenteric Bacilli.—Duke examined the feces of chickens, rats, dogs and rabbits besides human stools, and found frequently in them bacilli closely resembling *Bacillus dysenteriae* except in the response to agglutination and complement fixation. Animals were given true dysenteric bacilli on their food, and numerous other tests were made. All the testimony thus obtained speaks in favor of the assumption that dysenteric bacilli become modified outside of the body and lose their characteristics to such an extent that they come to resemble closely the dysenteriform bacilli that can be isolated from the normal human and animal intestine. Its motility, virulence for rabbits and agglutinating power may all decline, and the action on maltose and saccharose may change, but the action on mannite always persisted unmodified.

Nederlandsch Tijdschrift v. Geneeskunde, Amsterdam

May 3, 1919, 1, No. 18

The Work of Leonardo da Vinci. A. J. P. van B. Broek.—p. 1355.
Purpura. C. De Lange. p. 1564.
Paralytic Dementia or Poisoning. E. van Minnen.—p. 1746

Work of da Vinci in Anatomy and Biology.—Van den Broek analyzes da Vinci's extensive work in anatomy, biology and other branches of science, and expresses his amazement that the results of all this surprisingly accurate research did not seem to have any influence on the course of science in his day. It has been suggested that others plagiarized from him without mentioning his name. Not until the end of the last century and the first of this were his works compiled, and the discovery was then made that he must be regarded as one of the pioneers in modern anatomy, biology, etc. He studied for twenty years the question of aviation, declaring that the flying machine must be built on the principle of the body of the bird, so that the aviator "can balance himself and move through the air like a big bird, to the everlasting glory of the nest where he was born." And da Vinci died May 2, 1519! He studied plant life also, calling attention to the rings of growth in trees and explained why they were thicker on one side of the tree than on the other. The sea shells found on the tops of the mountains around Florence led him to a correct view of geological periods, so that the recent writer says of him "on créant la géologie il en a écrit un chapitre définitif." On one of his sketches is written in large letters, "The sun does not move." One of his aphorisms is that truth is always the daughter of her error.

Purpura. De Lange has over a dozen forms of purpura, he divides them in two great groups, those in which the

blood vessels are responsible and those in which the blood or the blood-producing organs are to be incriminated. The first group is the anaphylactoid type; the second group is the Werlhof disease type. Both types occur in a chronic intermittent form, an acute or a fulminating form, and the Werlhof type may occur as a symptom in leukemia or other diseases of the blood. She gives the minute details of eight cases of these various types, one the acute infectious form of anaphylactoid purpura in a child under 3 after an infectious sore throat and otitis. The blood platelets numbered only 71,750, but in two weeks they ran up to 1,130,000 and then settled back to an average between 213,000 and 718,000. Recurring epistaxis and hemorrhages from the buccal mucosa were accompanied by petechiae on the limbs and neck. The blood findings are tabulated over a period of six months, the hemoglobin only slowly increasing from 30 to 56 per cent, and the reds from 2,600,000 to 5,580,000. In one boy of 12 there was in addition an intra-abdominal hemorrhage. Tubercle bacilli seemed to be responsible in this case. De Lange cites further a family in which apparently infectious purpura developed in parents, grandmother and three children, all within a few days, and running a mild course in all. Only one of De Lange's eight cases was of the Werlhof type. This was in the young infant of parents both subject to epistaxis. There was nothing to indicate hemophilia otherwise, although there are many reasons for accepting a connection between idiopathic Werlhof's disease and hemophilia. The prognosis in this case seems grave; it may run into aplastic anemia. In treatment of acute purpura, extract of blood platelets should be systematically given when there is thrombopeny. With the anaphylactoid form, gelatin has often given good results, but when there is thrombopeny this should be given cautiously as we know that, in dogs at least, certain colloidal substances, such as gelatin, heterogenous-serums, etc., agglutinate the blood platelets, and they are then carried to the liver and destroyed.

Hygiea, Stockholm

June 16, 1919, 81, No. 11

Outcome after Tonsillectomy for Rheumatism. H. Nordlund.—p. 497.

Tonsillectomy and Rheumatism.—Nordlund devotes nine pages to tabulation of the details of 30 cases in which tonsillectomy was done to ward off recurring polyarticular rheumatism or hemorrhagic nephritis. This effect was realized in nearly every case, a large number having been free from recurrence since the operation. The results seem to be equally favorable whether the tonsillectomy was done during an acute attack or during an interval. The benefit was equally striking also in the 12 cases in which hemorrhagic nephritis had followed an infectious sore throat. In 6 of the 7 acute cases in this category, marked improvement was evident, but no modification was apparent in the other case nor in 3 of 5 chronic cases; the other 2 displayed pronounced benefit.

Analysis of Sensations. H. Olqvist.—p. 317.
Localization of Sensation of "Sweet Smell" of Chloroform, etc. E. Bergmark.—p. 384.
Motor Localizations in the Internal Capsule. G. Bergmark.—p. 401.
Excitability of the Brain in Young Infants. G. Bergmark.—p. 420.

Excitability of the Brain in Very Young Infants.—Bergmark describes the results of electric and other tests on an infant, 5 weeks old, with a large hernia of the brain. Delivery had been normal but the small hernia of the brain noted at birth rapidly increased until, as the illustration shows, the circumference of the hernia was larger than that of the head, the neck of the hernia measuring 4 and 6 cm. in diameter. There was no reaction to gentle palpation of the herniated brain tissue but the child screamed with strong pressure on it. Bergmark, assisted by Barany, applied various tests to the brain tissue which demonstrated localized responses to mechanical and thermal stimuli. The modifications under general anesthesia were interesting, as also the peculiar form of the motor response in the arm to pressure on the apex point in the neck of the hernia.

THE RELATION OF PATHOLOGY TO PRACTICE*

FRANCIS CARTER WOOD, M.D.

NEW YORK

With the swinging of the pendulum in the science of medicine has come the fashion of neglecting pathology, the pathology of the type called, in the olden days, morbid anatomy. This neglect is shown in many ways: in a diminution in the volume of published work; in the lessened number of necropsies performed, and in the smaller number of men who are actively interested in the subject. It may be that the great days of Rokitsky, of Virchow and of Cohnheim have passed never to return; but it is more likely that the next swing of the pendulum will bring with it a renewed interest in the study of the anatomic changes which accompany disease.

That, despite the recent progress in biochemistry and serology, there are still a few things to be learned in morbid anatomy has been shown by the recent rediscovery of the peculiar types of bronchopneumonia which have caused so heavy a mortality in those suffering from influenza, and by the large number of important studies on the lesions of toxic war chemicals.

Technical improvements in the methods of histology have lagged somewhat of late, except, perhaps, in neuro-anatomy, and it is not so easy to pick up a simple problem, or one promising considerable harvest with little labor, as it is in some of the newer subjects; but there is much yet to learn. Is the subject of nephritis, of cirrhosis, of myocarditis, of endarteritis, exhausted? Are not tumors still as baffling as they were a hundred years ago?

FAULTY MEDICAL INSTRUCTION

The lack of interest in pathology begins with the student. He is badly taught in many institutions. His course in anatomy and histology is usually ideal from a biologic aspect but ill adapted as a preliminary to the study of pathology. My own belief is that it would be better for the student of medicine if the occupants of the chairs of anatomy should be required to do research chiefly, and, except for special courses, should attend principally to graduate work. Most of the actual undergraduate teaching in anatomy might just as well be done by instructors, and all of the

latter should be graduates in medicine and made to arrange some correlation in the subject-matter of their courses to the facts taught in the clinical branches. With the present admission requirements, the assumed cultural value of anatomy may well be forgotten.

Secondly, pathology is badly taught chiefly because of the lack of necropsies. This is due not to the pathologist himself, but to the physicians and the surgeons of the hospitals, who no longer urge that necropsies be obtained as a routine. This is the reason why most of the able pathologists in the United States have been forced to obtain a large portion of their training in Berlin or Vienna. Now that these schools are no longer available, more effort should be made to raise the standard of the teaching of gross pathology in this country. Where can be seen today such brilliant demonstrations as Virchow gave in Berlin, or Kolisko in Vienna?

A third trouble with the student is that after he leaves the regular course in pathology he falls into the hands of men instructing in the clinical branches who often know less pathology than he does, impossible as the fact may seem. If the attempt is made to correlate the physical signs and symptoms of disease with the pathologic changes which underlie such signs and symptoms, the student is apt to be confused by the contradictions between the matter taught in the laboratory and that in the wards. To attempt to determine which teacher is right requires too great an expenditure of cerebral energy on the part of the student, and the knot is usually cut by forgetting both sides. So, as he progresses toward his hospital years or his practice, the student gradually sheds the thin epidermis of pathologic anatomy he at one time possessed, and enters into practical life with a mind unburdened by pathology. In most hospitals today he will see only a fraction of the necropsies that his seniors did about twenty years ago; or if such examinations are fairly frequent, he has little time from his ward duties, and therefore does the practical work, which interests him more than labors in the field of what he considers pure theory.

IMPORTANCE AND NEGLECT OF NECROPSIES

The physician of today also neglects the postmortem room, except in teaching hospitals. How seldom do we see the house staff and medical attendants remain through a complete necropsy, or attempt to study the detail of pulmonary, renal or cardiac lesions with a view to checking up physical signs or the stage of lesions.

He rarely obtains postmortems on his private patients, though the intelligent are often more willing

* Chairman's address, read before the Section on Pathology and Physiology at the Seventieth Annual Session of the American Medical Association, Atlantic City, N. J., June, 1919.

to give consent than the family of the ignorant denizen of the hospital ward. Nor does he, as a rule, although there are, of course, exceptions, urge on his staff the importance of the thorough investigation post-mortem as the only means of confirming opinions in doubtful cases. Only the pathologist realizes how many patients with hysteria have brain tumors; in how many heart cases there are no valvular lesions, but nephritis; and that 10 per cent. of all old persons die with unsuspected cancer. The result of this lack of interest is that the percentage of necropsies is steadily falling in many of our hospitals. If the Mayo Clinic and the General Memorial Hospital of New York succeed in obtaining a permit in over 50 per cent. of deaths, why does Bellevue Hospital obtain only 7 per cent. and many other institutions only from 20 to 30?

INADEQUACY OF FUNCTIONAL TESTS

There is little doubt that the reason so few necropsies are obtained is that the physician of today is more interested in functional tests than in morbid anatomy; and yet of what ultimate value to medicine is a dye excretion test, or a chlorid determination, or a blood urea or creatinin test unless the kidney lesions are also investigated? All these, perhaps more especially the blood sugar test, are of value in treatment and prognosis; but if they are ever to become a permanent part of our body of medical knowledge they must include some morphologic foundation.

It may be convenient and practical to classify nephritides into two groups: those who retain salt and those who do not; but such a method conceals an enormous amount of ignorance. The study of disease by the functional method is of enormous importance and has led to a great increase in our knowledge, but it should not attempt to stand alone and independent of all morphology.

An excellent example of the admirable results following a combined attack is the great advance that has been made in the past fifteen years in the correlation of anatomic findings with groups of clinical symptoms in the diseases of the nervous system. A very important part in this has been due to the discovery and wide use of new histologic methods and the Wassermann test; but the internist could well imitate the neurologists in their extremely laborious studies in the cellular pathology of the nervous system.

VALUE OF PATHOLOGY TO THE SURGEON

The surgeon, too, is not without a certain feeling that pathology is a somewhat dead if still annoying specialty. He is still displeased when told that he has excised only a portion of a tumor, or a secondary deposit and not the primary growth, that the spleen which he has just removed with the utmost skill contains nodules derived in all probability from a benign lump in the breast which some colleague had removed a year or so previous, and never submitted for microscopic examination. He still contributes to the joy of medical literature by such a choice morsel as this, culled from a recent surgical journal:

A large tumor successfully removed from the pelvis was reported by the pathologist as resembling thyroid tissue, whereupon the thyroid was carefully examined and found to be cancerous. "Nevertheless," remarks the operator with delightful freedom from logic, "it is not wise to rely on

microscopic examination of tumors; it is often misleading, and the physical examination of the mass at the time of operation is to be preferred."

So, too, the pathologist is blamed in a recent surgical article for not discovering the frequency of occurrence of perforating duodenal ulcer post-mortem, while the surgeon often sees the lesion and saves the patient. The obvious retort, that perhaps the reason such cases do not often come to necropsy is that the patients fortunately do not die of the disease, is to deny the advantages of early operation. Even the physician is not blameless according to certain surgical minds, for he does not yet realize that "the place to learn diagnosis and treatment is at the elbow of the surgeon," and one may, under these circumstances, venture to look forward to a medical elysium in which the crude methods now employed will be abandoned and diagnosis made definite and therapeutics infinite in power by the simple procedure of exposing the offending organ, studying its pathology in situ, and prescribing with a certainty now impossible. Such a time will be anxiously awaited by all but the patient.

SUMMARY

Pathology is today too largely confined to medical schools and teaching hospitals. As it is the foundation of all medicine, the student should be inspired to carry on its study as a part of his practical life. The physician must know and use it to temper his diagnostic and therapeutic enthusiasms. While the diagnosis and treatment of the individual suffering from disease is the art of medicine, we must not become so busy as to neglect the science of medicine which concerns the future of the race.

The surgeon also needs pathologic training to enable him to make a certain diagnosis when some unexpected lesion is discovered during the course of an operation. He needs tumor pathology above everything else, for unless he knows it, the operative results on cancer cannot be improved on as they should be. A knowledge of pathology, in other words, is essential for correct diagnosis, prognosis and treatment.

The Saliva in Pellagra.—M. X. Sullivan and K. K. Jones (*Public Health Rep.*, May 16, 1919) report that in this disease the condition of the mouth and particularly of the tongue is of considerable significance in establishing a correct diagnosis. The quantitative studies showed that salivation spoken of by the patients was often apparent rather than real and was seemingly due to some inhibition of swallowing combined with a peculiar, ropy change in the saliva which made its presence in the mouth more obvious. A tendency toward a greater quantity of solids in the saliva of pellagra patients was also observed. The diastatic power of the saliva of pellagra patients is at least as great as that of normal people. While the amount of mucus precipitated from saliva by acetic acid was greater for the saliva of the pellagra patients than for the controls, the increase is apparently unrelated to the severity of the symptoms. The sulphocyanate content of the saliva disclosed that this is much less marked than in the saliva of normal people. Since it is generally admitted that the sulphocyanate arises from the metabolism of protein and the detoxicating action of the system, whereby poisonous cyanids are converted into the relatively innocuous sulphocyanate, the investigators believe that in pellagra patients there is both a lessened protein intake and a detoxicating power feebler than normal. The reaction of the saliva in pellagra is somewhat more alkaline than is that of normal saliva.

SURGICAL TREATMENT IN THE BLEEDING TYPE OF GASTRIC AND DUODENAL ULCER*

D. C. BALFOUR, M.D.
ROCHESTER, MINN.

The surgical treatment of uncomplicated benign lesions of the stomach and duodenum has reached a high state of efficiency and standardization. The

hematemesis. Some of these conditions do not fall within the field of the surgeon, but there are other conditions which can be eradicated by surgical means, and this group is so important that I shall review briefly a representative example, a case illustrating the diagnostic error of presupposing gastric ulcer because of hematemesis, and of following the error by carrying out a routine operation on the stomach designed to cure this imaginary ulcer:

A man (Case 132411), aged 55, came to the clinic, June 5, 1915, because of recurring hematemesis. In some of the attacks the patient had been almost exsanguinated. The hemorrhages had begun in January, 1914, without a previous history suggestive of a causative factor; in July, 1914, a gastro-enterostomy was performed at his home; he was told that an ulcer was found at the pylorus. Some weeks after the operation a hemorrhage occurred similar to those he had had before the operation, and between that time and his registration in the clinic he had had several distinct gastric hemorrhages, the last severe one occurring in February, 1915. There were no typical symptoms nor physical or laboratory findings to establish a diagnosis, but the patient's condition and history were such as to make further exploration imperative.

In July, 1915, I explored and found a patent and well functioning gastro-enterostomy. Palpation revealed no induration in stomach or duodenum, and no visible signs of ulcer, nor did careful inspection through a large opening in the anterior wall of the stomach show any evidence of an active or healed ulcer at the anastomosis or in the stomach or duodenum. Exploration of the biliary tract disclosed a slight thickening of the walls of the gallbladder through which the yellowish spots on the surface of the mucous membrane which indicate a cholecystitis of the "strawberry" type could clearly be seen. The pancreas, too, showed very distinct changes, being considerably enlarged and nodular. This fact, the gall-

Fig. 1.—Shaving of thickened musculoperitoneal coats.

various complications, however, which may develop in direct connection with gastric and duodenal ulcer, such as acute and chronic perforation, obstruction, deformity, malignant degeneration, and hemorrhage, present added problems to the surgeon; one of the most important of these is hemorrhage.

Gastric hemorrhage has been the occasion of more confusion in diagnosis, uncertainty in therapeutic indications, and irrationality in treatment, both medical and surgical, than perhaps any other gastric condition. The number of cases seen in which an erroneous interpretation of symptoms has led to incorrect suggestion for treatment, resulting in failure to protect the patient against further hemorrhage, illustrates the necessity of persistent study of the subject. This paper is concerned chiefly with two groups of cases, first, those in which operation has proved unsatisfactory because of error in attributing the bleeding to a lesion which is not present, and second, those in which the surgical procedure carried out has failed to obviate further hemorrhages, even though a correct diagnosis has been made.

A study of these groups disclosed certain facts which indicated that it should be possible to decrease the incidence of such failures; in the first group, by more accurate preoperative diagnosis, with better interpretation of operative findings; in the second group, by the addition of certain specific measures to the standard surgical procedures applicable to benign lesions of stomach and duodenum.

The first group of cases, those in which no intrinsic lesion is present, not only is large but also includes a variety of conditions which may be associated with

Fig. 2.—Probe introduced through the site of chronic perforation.

bladder findings, and past experience in similar cases, seemed a clue to the cause of the hematemesis. There were no recognizable changes in the liver, and general exploration was negative. A cholecystectomy was performed because in our experience with cholecystitis, with or without stones, associated with pancreatitis, and without jaundice, this has seemed

* Read before the Section on Obstetrics, Gynecology and Abdominal Surgery at the Seventieth Annual Session of the American Medical Association, Atlantic City, June, 1919.

the operation of choice. A well defined chronic catarrhal cholecystitis of the most typical "strawberry" type was found. The patient made an uneventful recovery and has had no hemorrhage since. Similar cases in which the appendix, spleen or liver is the basic focus are not infrequently seen.

The first question, then, to demand a decision in cases of gastric or gastro-intestinal hemorrhage concerns the cause of the hemorrhage. Fortunately, in the majority of cases careful history taking, associated with expert interpretation of roentgen-ray findings, will usually determine whether or not an ulcer is present. If the evidence does not support a diagnosis of ulcer, but indicates disease in some organ in the abdomen, such as the gallbladder, pancreas or appendix, it must not be forgotten that gastric hemorrhage

sic to the stomach are found which, when eradicated, secure permanent protection against further hemorrhage. In hematemesis unassociated with abdominal symptoms or findings, and in which it is not possible to establish a diagnosis, operative interference should, as a rule, be advised against.

The group of cases, however, to which I particularly refer is that group in which recurring gastric hemorrhage has been caused by a chronic gastric or duodenal ulcer. Our records show that 25 per cent. of gastric ulcers and 20 per cent. of duodenal ulcers have been complicated by one or more gross hemorrhages. In the earlier days of gastric surgery the operation of gastro-enterostomy proved to be so efficient in a large majority of benign lesions of the stomach and duodenum associated with hemorrhage that the realization came rather slowly that at least some of the failures to obtain a complete cure, including protection against further hemorrhage, could be attributed to the fact that direct attack on the ulcer was not added to the indirect therapeutic measure of gastro-enterostomy. The recognition of the danger of malignant degeneration in gastric ulcer gave the first impetus to the practice of combining gastro-enterostomy with the radical excision or destruction of such ulcers. The advisability of such a principle is now well established.

It has, therefore, become quite evident that in the surgical treatment of a gastric or duodenal ulcer which has been the cause of hemorrhages, some direct attack on the ulcer is most important. The necessity for this has become apparent to us because of the fact that a number of our own patients with duodenal or gastric ulcer had failed to secure, by gastro-enterostomy alone, protection against further bleeding. Apparently rare as such failures were, they nevertheless formed in the aggregate a group which called for an investigation as to the possibilities of reducing the number of such recurrences. A concise compilation of such cases illustrating the incidence of hemorrhage as a late postoperative complication may be found in the accompanying tables. The cases chosen for study were those in which operation was performed in the Mayo Clinic during the twelve year period between January, 1906, and January, 1918.

A study of Table I, which represents the percentage of hemorrhages following operations for duodenal ulcer, shows that 12.7 per cent. of the patients who had hemorrhages before operation had hemorrhages after operation, and in two instances the hemorrhages were sufficient to cause death. Twenty patients (0.9 per cent.) in the group who had not reported hemorrhages before operation had hemorrhages following operation. Eighty-three patients, 2.8 per cent. of the total number operated on, had hemorrhages following operation.

Fifteen patients (8 per cent.) with gastric ulcer report hemorrhage after operation who had had hemorrhage before, and two patients (0.3 per cent.) had hemorrhage who had not had hemorrhage before

Fig. 3.—Peritoneal surface of ulcer prepared for application of cautery.

may be due to such extrinsic causes. The spleen and liver particularly should be kept in mind as causative factors, for it has been proved that either the spleen or the liver or both can be the cause of most serious gastro-intestinal bleeding without showing any changes that are recognizable in our present state of knowledge. The group of cases in which an undoubted gastric hemorrhage has occurred but in which the symptoms or physical findings are insufficient to lead to a positive diagnosis either of ulcer or extrinsic trouble requires, therefore, the most serious consideration as to whether operation should be undertaken. Fortunately, symptoms are usually associated with such hematemesis, and, though obscure, justify an exploration, and although doubt may exist as to any satisfactory explanation being found to account for the hematemesis, frequently pathologic conditions extrin-

operation. Seventeen patients, therefore, suffered from hemorrhage after operation, a percentage of 14 of the total number of gastric ulcers operated on.

A comparison of the figures in Tables 1 and 2 shows that the incidence of hemorrhage in duodenal ulcer following operation is definitely higher than the incidence in gastric ulcer, notwithstanding the fact that

there is a greater tendency for gastric ulcer than for duodenal ulcer to be complicated by bleeding. This important fact, namely, the difference in operative

possibilities of becoming malignant. Excision of such ulcers either by knife or cautery was, therefore, performed whenever possible by surgeons whose experience was sufficient to make them appreciate the necessity of this treatment. Such radical measures neces-

Fig. 3.—Ulcer of the duodenum apparently healed but the cause of recurring hemorrhage. Silk suture which had been placed at a previous operation.

sarily carry a higher operative mortality, but the avoidance of such mortality by simpler operative measures means a marked increase in ultimate morbidity and mortality.

In duodenal ulcers, however, radical treatment was not necessary because of this possibility of malignant degeneration or of disabling complications, and the indirect method of treatment by gastro-enterostomy

Fig. 4.—a, cauterization over a small duodenal ulcer; b, completed operation; omentum implanted over site of closure.

results in gastric and duodenal ulcers, may be largely attributed to essential differences in operative technique.

The radical treatment of gastric ulcer was originally due to the recognition of the fact that an ulcer on the gastric side of the pylorus holds unquestionable

proved to be sufficient in a high percentage of cases to relieve the patient of the symptoms of which he complained. The more frequent occurrence of hemorrhage after operation for duodenal ulcer than for gastric ulcer is apparently due to this difference in operative procedure, and the following facts bear out such a statement: In not one of the eighty-three cases in which hemorrhages occurred after operation for duodenal ulcer was the combined operation of excision of the ulcer with gastro-enterostomy carried out, and with the exception of eight cases in which various types of pyloroplasties were performed, in every case a gastro-enterostomy alone was performed. This fact

is significant particularly when one compares the results of the established methods of excision and gastro-enterostomy in gastric ulcer in which, although the tendency to hemorrhage had been greater, a much smaller percentage of bleeding followed operation. The combined procedure of excision and gastro-enterostomy was carried out in only one of the seventeen cases of gastric ulcers in which there was bleeding after operation. These facts can only mean that the methods of direct attack combined with gastro-enterostomy which are used in the treatment of gastric ulcer are a source of protection to the patient against further hemorrhage.

Another point brought out in the study of these cases is that in the majority of those patients who had bleeding after operation, the operation relieved all other symptoms, so that the recurrence of the complication of hemorrhage was the only feature which marred an otherwise perfect result. This fact is difficult to explain. It raises the question, for example, whether the hemorrhage actually comes from the site of the symptomless ulcer. The fact that the mucous membrane can bleed when no visible lesion is present, and that recurring hemorrhages from the stomach may take place without any demonstrable changes either in the stomach or in any other organ, throws some doubt on the assumption that all such recurrences have their origin at the site of the ulcer.

led to a thorough search for some means of lowering the incidence of these failures. From a study of our own cases it was perfectly evident that gastro-enterostomy alone, as I have pointed out, is insufficient protection against further hemorrhages, and that excision

Fig. 7.—a, cauterized opening closed by row of catgut; b, closure reinforced by a mattress second continuous suture.

combined with gastro-enterostomy has given almost total protection. The problem resolves itself, therefore, into one which concerns the safest method of accomplishing a radical excision in the majority of cases. Various suggestions have been made and carried out at different times. Ligation of the vessels in the circumference of the ulcer, a procedure highly recommended by Woolsey,¹ devitalization by constricting suture, pyloric exclusion of von Eiselsberg,² and excision have all been tried. Unfortunately, under certain circumstances knife excision is a formidable technical procedure and one at which even the experienced surgeon will wisely hesitate. In a search for some method which will be at the same time radical, safe and applicable in the largest number of cases, we have adopted the actual cautery as meeting these requirements.

TECHNIC

The technic for the use of the cautery in the bleeding type of gastric ulcer differs in no particular from that used in the ulcer which has not been associated with bleeding; it may be briefly described by stating

¹ Woolsey, G.: The Surgical Aspects of Gastric Hemorrhage, New York, M. J., 1917; 395-398 (March, 9, 1918).

² Von Eiselsberg, L. A.: The Choice of the Method of Operation in the Treatment of Gastric and Duodenal Ulcer, With a Review of the Experience Accumulated in the Past Ten Years, Surg., Gynec. & Obst., 1912; 255-263 (Nov., 1, 1914).

Fig. 8.—a, cauterized area closed with catgut; b, exposure by first row chromic suture.

But the fact remains that in the majority of cases in which we have reoperated, radical treatment of the ulcer area obviated further hemorrhages.

Our gradual radicalization of these facts, particularly when we found that 12 per cent. of duodenal and 8 per cent. of gastric ulcers which had been the source of bleeding before operation bled after operation,

its important features.³ Probably the most important point in this technique is the exposure of the peritoneal side of the ulcer, and, in a great many instances, as we have recently demonstrated, a close shaving of the gastrohepatic omentum (Fig. 1) with a portion of the thickened peritoneal coat will disclose the minute opening which marks the site of chronic perforation. In many cases a probe may be introduced (Fig. 2) through this tract and used as a guide in introducing the cautery (Fig. 3). This observation seems important because it shows the frequency with which this perforation can be demonstrated, and that chronic perforation occurs in practically all chronic ulcers. Knowing from palpation the size of the crater of the ulcer, the cauterizing is maintained until an opening as large as the crater is made. In this way, as I have pointed out in previous articles,⁴ any malignant cells within an area of 2 cm. of the cautery point are killed, and the danger of cancer-cell grafting, which is always present in knife excision, is avoided. The opening is subsequently closed with fine chromic catgut, and with reinforcing sutures of silk.

Cauterization is simpler in duodenal than in gastric ulcers, as the duodenal ulcer is usually in direct view and is rarely protected by any surrounding tissue; moreover, the crater of the ulcer is often very small, so that only puncture of the ulcer is required (Fig. 4 *a* and *b*). The cautery in duodenal ulcer was first employed in ulcers of the bleeding type, but lately it has seemed advisable to destroy, in this manner, practically all duodenal ulcers which are readily accessible (Figs. 5, 6 *a* and *b*, and 7).

SUMMARY

The points I desire to emphasize are:

1. Hemorrhage following operations for both gastric and duodenal ulcer is of sufficient frequency (2 per cent. in duodenal ulcer and 1+ per cent. in gastric ulcer) to warrant a revision of operative methods in such cases.

2. Gastro-enterostomy or pyloroplasty alone does not always protect against further hemorrhages, while excision of the ulcer and gastro-enterostomy gives almost total protection.

3. Excision by cautery combined with gastro-enterostomy is the most satisfactory method in the majority of cases of minimizing the possibility of recurrence of hemorrhage in all ulcers which have been associated with hemorrhages, and similar treatment seems advisable in both gastric and duodenal ulcers which have not exhibited such a complication.

4. Balfour, D. C.: *Ann. Surg.* **67**: 725-731 (June) 1918; Treatment by Cautery of Gastric Ulcer, *Surg., Gynec. & Obst.* **10**: 525-530 (Oct.) 1914.

The Venereal Toll.—During the month of September, 1916, from nearly 42,000 Canadian troops in Great Britain there were admitted to hospital suffering from venereal disease, 960 men, practically a battalion; during the month of September, 1918, from among 110,000 Canadians in Great Britain there were 750 similar admissions. In two years the venereal incidence had been reduced more than 66 per cent. It stands now at less than the third of what it was two years ago. Had they continued at the same rate, the admissions during the month of September, 1918, would have been, not 750, but over 2,500; not seven and a half companies, but two battalions and a half out of action.—Adami, *Canad. M. J. J.*

A NEW OPERATION FOR DUODENAL AND GASTRIC ULCER *

J. SHELTON HORSLEY, M.D.

RIEHMOND, VA.

There is no excuse for a new operation if the old ones are satisfactory. The results of a surgical operation are the test of its efficiency, and they should be viewed from two standpoints: First, and most important, is the clinical result and, secondly, the restoration of tissues or organs to their normal physiologic condition. It seems probable that no important physiologic function of the body can be abolished or seriously altered without creating a disturbance of health in at least some of the individuals thus affected.

The usual surgical treatment for duodenal or gastric ulcers is gastro-enterostomy, with or without excision of the ulcer. When done for gastric ulcer, the ulcer is either excised or cauterized with the actual cautery (Balfour). When the gastro-enterostomy is for a

Fig. 1.—The incision is made from a point on the anterior surface of the duodenum not farther from the pylorus than 1 inch, extending into the stomach, midway between the greater and lesser curvatures, not less than two inches. These points are fixed with forceps or sutures before the gauze is placed.

duodenal ulcer, the ulcer is usually not excised, but is often sutured over or folded in. Another type of operation employed is the pyloroplasty of Finney.

GASTRO-ENTEROSTOMY

The clinical results from gastro-enterostomy when performed for duodenal or for gastric ulcer are by no means perfect. D. C. Balfour¹ says:

Although evidence is conclusive that surgery gives permanent relief in a higher percentage of cases and with less associated risk than any other therapeutic measure, it is also true that the surgical treatment of gastric ulcer may be made still more efficient.

He reports end-results of 285 cases of gastric ulcer in which operation was performed at the Mayo Clinic from Jan. 1, 1900, to July 1, 1915, with 159 (55.7 per

* Read before the Section on Obstetrics, Gynecology and Abdominal Surgery at the Seventeenth Annual Session of the American Medical Association, Atlantic City, June, 1919.

cent.) cures. The rest are classified as "greatly improved," "improved," and "unimproved."

Frank Smithies of Chicago, who was formerly gastro-enterologist at the Mayo Clinic and is now at the Augustana Hospital of Chicago, has long been associated as a medical man with large surgical clinics in which gastro-enterostomy is the chief surgical method of dealing with gastric or duodenal ulcer. He² reports observations on 273 patients on whom

Fig. 2.—The opening in the stomach has been made; first, by cutting down to the gastric mucosa and clamping as many vessels as possible before opening the mucosa; then the incision is extended into the duodenum for not more than one inch. The ulcer is excised from the mucous surface.

gastro-enterostomy had been done for the relief of dyspepsia. His paper was intended as a study of the function of the stomach after gastro-enterostomy, but the side-lights on the efficiency of this operation as a therapeutic measure are illuminating.

Smithies' 273 cases represent 226 patients operated on for gastric or pyloric ulcer, twelve for gastric cancer, and thirty-five for duodenal ulcer not involving the pylorus. Of this entire number, he reports only fifty-seven, or 20.9 per cent., clinically complaint free. Twenty-eight* (80 per cent.) of the thirty-five duodenal ulcer patients had pain or distress, and many of this number had other symptoms, such as gas, nausea, vomiting, or eructation. However, as the total number of cases is made up of (1) patients requested to return for examination regardless of their condition and (2) patients who came voluntarily because they were having trouble, the percentage of cures represented is too low. In reply to a request, Dr. Smithies has written me under date of April 10, 1919, that about 65 per cent. of the 273 patients (177) returned for examination at his request. Percentage based on this number (177) would be mildly favorable because these cases were selected apparently arbitrarily from a large number of stomach cases in which operation had been performed and which had been observed by him (2,360) and do not include those patients who came voluntarily because of trouble. Making all allowances for this latter group, which constitutes about one third of the total number, we still have a percentage of complaint-free patients that is very low (much below 50 per cent.) both for gastric and for duodenal ulcer patients on whom gastro-enterostomy had been done.¹

These results as reported by Balfour and by Smithies certainly cannot be considered satisfactory so far as curing the patients is concerned.

It is obvious that gastro-enterostomy for duodenal or gastric ulcer does not restore the stomach to its normal physiologic condition. The clinical cures following this operation have been variously explained. Some have said that it is a gravity drainage operation, and yet in draining other hollow muscular viscera we do not open at the lowest point. The gallbladder and the urinary bladder are drained from the part opposite the most dependent portion, and an enterostomy is done on the loop of intestine nearest the obstruction and not on the loop deepest in the pelvis; for we know that normal contraction or peristalsis will keep the bladder or bowel empty if an opening is made. From time immemorial the current of pressure and the peristaltic rhythm of the stomach have been focused on the pylorus, and not on the so-called lowest point in the stomach. Besides, there is no one portion of a mobile muscular organ, such as the stomach, that is always at the lowest point. This and other disadvantages of gastro-enterostomy have been admirably demonstrated by Cannon and Blake.⁵ It has been affirmed that gastro-enterostomy cures by short-circuiting the course of food and so resting the ulcer; and also that it cures by lessening the acidity of the gastric juice. The roentgen ray has shown that unless the pylorus is closed some food usually continues to go by this route and pyloric closure is not often permanent unless a resection is done.

Lemander's⁶ statement that the stomach is without sensory nerve supply for pain has been apparently disproved. Other investigations⁷ seem to have shown that the stomach has a limited supply of nerves that conduct pain. These nerves terminate in the muscular coat of the stomach, and do not reach the mucosa. It has been demonstrated that the pains that come on with

Fig. 3. If there is marked stenosis, pockets will result on the duodenal side. These are obliterated by incisions of the mucosa and of the constricting bands. To avoid hemorrhage these incisions should be short and not too deep.

such clocklike regularity after meals in duodenal or gastric ulcer are not caused by acid erosion of the ulcer by the hyperacid gastric juice, as was formerly believed, but are due to the pressure of peristalsis on

these gastric nerves, which are made unusually sensitive by the inflammation of the ulcer.⁸ Consequently, they register impulses of pain from the pressure of peristalsis that in a normal physiologic condition they would not register. The character of the gastric juice has nothing to do with the pain except so far as it excites peristalsis. Gastro-enterostomy probably relieves the pain from a duodenal or gastric ulcer by facilitating the emptying of the stomach, thus lessening

to be better than after gastro-enterostomy. Finney and Friedenwald say that the contraindications for this operation are inability to mobilize the duodenum, and thickening and infiltration about the pylorus.

Finney's operation, while a distinct improvement on gastro-enterostomy, is not free from objections. It seems to have been conceived partly with the idea of making it a gravity drainage operation, when, as already pointed out, drainage of a hollow muscular organ, such as the bladder or bowel, does not have to be from the lowest point in order to be effective. Mobilization of the duodenum, which is necessary for this operation, may be quite difficult and, according to Finney, where numerous adhesions exist, his operation often cannot be done. The incision is made near the greater curvature of the stomach, where the vessels are large. The pylorus is divided in such a manner that it cannot reunite, and its sphincteric action would seem to be permanently impaired. If there is cicatricial contraction at the pylorus, the scar tissue must be sutured to scar tissue, for the apex of both the posterior and anterior margins of the sutured wound are at the pylorus.

Fig. 4.—The incisions in the mucosa dividing the bands are sewed up transversely, and, if necessary, along the upper and lower border of the stenosis the mucosa of the duodenum is sutured to the mucosa of the stomach. It is essential to have a complete mucous membrane covering for the posterior wall.

peristalsis. This is largely the treatment of a symptom and not an effort to remove a pathologic condition and restore tissues to their physiologic state.

The dangers of vicious circle, jejunal ulcer, volvulus, or hernia into the lesser peritoneal cavity, though not great, yet exist when a gastro-enterostomy is done and are not present in operations on the pylorus.

FINNEY'S PYLOROPLASTY

When pyloroplasty is done, the method usually employed is that of Finney. Finney's operation, as is well known, consists of a horseshoe-shaped incision with its center at the pylorus, one limb extending down on the mobilized duodenum, and the other on the stomach near the greater curvature. These limbs of the incision are united by suturing the posterior margin of the wound in the duodenum to the posterior margin of the wound in the stomach, and the anterior margin of the wound in the duodenum to the anterior margin of the wound in the stomach. Many of the objections that apply to gastro-enterostomy do not obtain here, as the operation is done at the normal physiologic outlet of food from the stomach. Finney and Friedenwald⁹ report a group of 100 cases in which operation was performed by Finney's method. Five of the patients died soon after the operation. The final results in seventeen are unknown, as the patients could not be traced. Of the remaining number, results are classified as being satisfactory in seventy-three, or 93.6 per cent. of those traced. It is not stated whether the term "satisfactory" means "complaint free." If it does, the results are excellent, but, if not, it would be difficult to compare these statistics with those of Balfour or of Smithies. At any rate the results appear

HEINEKE-MIKULICZ OPERATION

The Heineke-Mikulicz operation, which was conceived to remedy pyloric stenosis, is generally supposed to be a straight incision with its center at the pylorus or at the point of constriction, the incision being sewed up transversely. Such is the description of the Heineke-Mikulicz operation as it appears in many textbooks.¹⁰ In Binnie's *Operative Surgery*, 7th edition, p. 385, a description is given of this operation that resembles somewhat the Finney operation. However, the Heineke-Mikulicz operation in its usual conception as being a straight incision with its center at the point of constriction or at the pylorus, the incision being

Fig. 5. In the first step of closing the incision, a suture of tanned catgut is inserted from the end of the stomach incision to the end of the duodenal incision. Then a second suture is placed half way between this suture and the upper angle of the wound.

sewed up transversely, finds but few advocates. Grey Turner¹¹ reports a small series of cases done by this method in which the results are quite satisfactory. As a rule, however, these objections are made to the Heineke-Mikulicz as ordinarily performed: 1. It cre-

ates a pouch with a slight constriction on the stomach side and on the duodenal side. Half of this pouch is made of the duodenum whose walls are much weaker than the walls of the stomach and it may be difficult to empty such a pouch. 2. The incision cannot be made very long because it would extend too far into the duodenum, which would have to be mobilized, and even then the tension of the sutures on the thin duo-

Fig. 6.—These two interrupted sutures are tied, their ends left long, and the suturing is begun at the lower angle with a curved needle and fanned catgut. A continuous lock stitch is used which gently approximates the mucosa. The two interrupted sutures, with the ends left long for traction, greatly facilitate suturing.

denal wall would be too great. 3. When stenosis exists, each end of the sutured wound consists of scar tissue which is sutured to scar tissue, for the center of the incision is at the point of constriction. 4. There is a tendency in healing for the pylorus to be drawn up high under the liver.

THE NEW PYLOROPLASTY

There is one part of the body in which an ulcer in the region of a sphincter has been the object of surgical observation since the earliest times of recorded surgery, and the treatment of this condition has become satisfactorily standardized. This is ulcer or fissure in ano. The analogy between an ulcer in ano and a duodenal or pyloric ulcer of the stomach which is in the region of the pyloric sphincter is striking. We know that the ulcer in ano does not heal readily because of the almost continuous action of the sphincter ani, which alternately compresses or relaxes the tissues in its neighborhood, and that in order to cure it we must employ the principle of physiologic rest and paralyze the sphincter temporarily, and at the same time excise or cauterize the ulcer. In this manner we remove the pathologic condition and institute rest for these tissues. We would not think of treating a fissure in ano by doing a colostomy and side-switching the fecal contents, particularly if the colostomy permitted a small amount of fecal matter to continue to pass through the anus; and yet in performing a gastro-enterostomy for the cure of a pyloric or duodenal ulcer we are practically doing just this very thing. By using the well known surgical principles that have been established for years for the treatment of fissure in ano, namely,

temporary paralysis of the sphincter and excision or cauterization of the ulcer, we can cure practically 100 per cent. of such cases. If, then, the ulcer in the duodenum or pylorus is not cancerous and is the only pathologic lesion, have we not a right to expect as good results here, so far as ultimate cure is concerned, by excision of this ulcer and temporary paralysis of the sphincter muscles, as has been obtained since the early days of surgery by similar treatment of an ulcer within the region of the sphincter ani? The operation here proposed has been conceived on these principles, and an effort has been made to carry them out as far as possible, at the same time avoiding the objections that have been noted to other types of pyloroplasty. The steps of the operation are:

1. The upper portion of the duodenum and the pyloric end of the stomach are exposed through an ample abdominal incision, and a point is selected in the midline of the anterior surface of the duodenum an inch from the pylorus, and another point on the stomach not less than two inches from the pylorus and midway between the greater and lesser curvatures (Fig. 1). Each of these points is grasped with Allis forceps or fixed with a suture. The stomach and duodenum are then surrounded with moist gauze.

2. An incision is made with a sharp knife from the point on the duodenum to the point on the stomach. If the ulcer is in the anterior surface of the duodenum, the incision should pass along the lower edge of the ulcer (Fig. 1). An effort is made to divide the peritoneal and muscular coats without opening the mucosa. The incision should go no farther than 1 inch into the duodenum. It extends 2 inches or more into the stomach. The bleeding points or exposed vessels are clamped.

3. The mucosa is incised and any further bleeding points are clamped, care being taken to include as little of the mucosa in the grasp of the forceps as possible. The vessels are tied with catgut (Fig. 2). If there is a tendency for duodenal contents to regurgitate, gauze wrung out of warm salt solution is gently packed into the duodenum. Moist gauze

Fig. 7.—A second row, mattress or right-angle sutures, is placed, burying the first row in the mucosa; and then a third row, which takes up the peritoneum and muscle, buries both the other rows.

can also be placed in the stomach if necessary. If the ulcer is along the incision, it is excised from the mucous surface and the forceps, scissors, and knife used in the excision are laid aside, as they are probably septic. Because the mucosa in this region is almost free from bacteria except in the ulcer, there is no occasion to disinfect the normal mucosa, as there would be in operations on the intestine lower down.

4. If the ulcer is in the posterior wall of the duodenum or pylorus, the wound is retracted, the ulcer exposed and

excised, the deeper structures are sutured with tanned or chromic catgut, and the mucosa is gently approximated by a continuous suture. The suture in the mucosa must not be tight, as this might cause necrosis of the mucosa and spread the ulcer. If there is an old contraction resulting in pockets, the mucosa and the contracting band should be divided and the mucosa sutured transversely to the incision. To avoid hemorrhage, the incision that relieves the contracting band should be short and should divide only the superficial part

interrupted stitches of fine catgut. Care should be taken that it barely covers the upper end of the sutured wound and that it is not fastened to the gastrophrenic omentum, as this might result in too complete a surrounding of the pyloric end of the stomach (Fig. 8).

9. If the ulcer is not in the duodenum or the pyloric region, the operation, as just described, may be done in order to relieve the spasm of the pylorus and the ulcer then excised, or cauterized, as advocated by Balfour, through another gastric incision.

The advantages of this operation are:

1. It removes the obstruction and the pathologic condition, and permits the normal resumption of the stomach function.

2. The ends of the sutured incision are within the stomach wall. The ratio of the incision should never be less than two parts in the stomach to one in the duodenum. Usually 2 inches in the stomach and 1 in the duodenum are sufficient. The anterior stomach wall in the midline can readily be pulled over to the first inch of the duodenum. In the Heineke-Mikulicz operation, and also in the upper part of the Finney operation, the ends of the sutured incision are in the scar tissue at the pylorus, while in this operation the ends of the sutured incision are within the healthy stomach wall, and the scar tissue that may remain about the pylorus is approximated, not to other scar tissue, but to healthy stomach wall. Consequently, union should be more satisfactory than where scar tissue is opposed to scar tissue, as in the other two types of pyloroplasty.

3. There is no pouch formation as in the Heineke-Mikulicz operation, in which the center of the incision is at the pylorus. The operation merely changes the shape of the pyloric end of the stomach from a funnel with gradually approaching walls to a rectangle that empties into a funnel with a more obtuse angle.

4. The parts to be put at rest are the parts most concerned in contraction and relaxation, which are the pylorus and the adjacent portion of the stomach. By making the incision from the duodenum about 2 inches into the stomach, this is effected. A long incision into the duodenum does not help in any way.

Fig. 8.—A piece of gastroepiploic omentum is brought over the incision and fastened with interrupted stitches of tanned catgut. Inset (a) shows, diagrammatically, that the pylorus is widened but not destroyed, that the outer end of the stomach is converted from a cone to a rectangle, and that there are no constrictions or pockets.

of the band. The neglect of this precaution resulted in a fatal secondary hemorrhage in my last pyloroplasty (Figs. 3 and 4).

5. The ulcer having been removed or pockets and contractions remedied, the ends of the incision are approximated by a tanned or chromic catgut suture (Fig. 5). A second suture of similar material placed half way between this middle suture and the upper angle of the wound renders suturing the upper half of the incision easier. Both are tied and their ends left long to facilitate suturing and to hold up the edges of the wound if there is a tendency of gastric or duodenal contents to overflow. A No. 1 tanned or chromic catgut suture is then started at the lowest portion of the wound, which is in the stomach wall. It is tied, the short end clamped, and the mucous membrane united by a lock stitch which barely approximates the mucosa and ends at the upper portion of the incision, which is also in the stomach wall. Before completing this suture any gauze packing in the duodenum or stomach is removed. The suture is tied at the upper portion of the wound and the ends are left long and clamped (Fig. 6).

6. A second row of sutures, consisting of the same kind of catgut, in a curved round needle, is inserted, taking in the muscular coat. This is a continuous mattress or right-angle stitch. Only enough tissue is included in the sutures to secure a firm hold. The long ends of the previous row are cut short.

7. A third row of sutures of fine tanned or chromic catgut is placed, but the gauze around the stomach and duodenum should be removed before this third row is begun, as gauze packing hinders the approximation of the peritoneum. This row includes the peritoneum and muscular coats and buries the first and the second rows of sutures completely. This is also a continuous mattress suture (Fig. 7).

8. A portion of the gastroepiploic omentum, or else the right edge of the great omentum, can be brought up over the line of incision without tension. It is fastened here with

Fig. 9. Drawing of stomach removed at autopsy of A. R. The incision was made in the posterior wall of the stomach. Note the ulcer that involves the lesser curvature and the large blood vessel protruding in the ulcer. Also note the healing of the pyloroplasty, which it does a wide opening. The patient died from hemorrhage from the gastric ulcer twenty-one days after operation.

5. The function of the pylorus and pyloric end of the stomach is not permanently destroyed. The stomach wall that is brought over acts as a link between the ends of the pyloric sphincter, and, in the course of time (usually a few weeks), the sphincter resumes its action, though, because it has been enlarged, it cannot become spastic as it was before the operation.

6. The operation is simpler than the Finney operation, in which the duodenum has to be mobilized and the posterior and the anterior margins of the wound must be sutured separately.

There is a superficial resemblance between this operation and the Heineke-Mikulicz, because in both operations the pylorus is divided and in both the incision is approximately straight. Here, however, the resemblance ceases, and the differences become marked. For, unlike the Heineke-Mikulicz, the operation described was conceived on the principle of giving temporary physiologic rest to tissues in the pylorus and the pyloric end of the stomach; the incision is longer than in the Heineke-Mikulicz operation; it is differently placed; it extends no more than 1 inch into the duodenum nor less than 2 inches into the stomach; it can be considerably prolonged at the stomach end; it gives an excellent view of the pyloric end of the stomach; it requires a rather definite technic to be closed satisfactorily; it does not form a pouch with a constriction fore and aft; it does not approximate scar tissue to scar tissue, and an essential part of the operation is the removing or remedying of the pathologic condition by excising the ulcer, obliterating pockets, or

day after operation, when milk is added to the diet. About the seventh or eighth day after operation a purgative is given and soft diet is begun.

CLINICAL REPORT

The first operation of the new pyloroplasty was done on Mrs. G. A. H., April 4, 1918. Five days later, April 9, I did a gastro-enterostomy on a man with duodenal ulcer. In the case of Mrs. G. A. H., gastro-enterostomy could not be performed because there were extensive adhesions in the lesser peritoneal cavity. Gastro-enterostomy was done on the man because I was not then assured of the full value of the pyloroplasty. Mrs. G. A. H., however, made such a satisfactory recovery that I have done the pyloroplasty in every case of duodenal or gastric ulcer since April 9, 1918, and since that date I have not done a gastro-enterostomy.

I have so far done eleven of the new pyloroplasties. Three of the operations were for gastric ulcer, two being for ulcer in the cardiac portion of the stomach on the posterior wall near the lesser curvature. In both of these cases, the ulcer was in a similar location and was reached through an incision in the anterior wall of the stomach.

CASE 1.—A. R. was operated on Sept. 23, 1918, for gastric ulcer. The ulcer had not quite perforated, though the peritoneum appeared to be slightly adherent behind. The margins of the ulcer were excised, the mucosa was brought together with mattress stitches of tanned catgut, and then the pyloroplasty was done. The patient made an uneventful recovery from the operation and appeared to be doing well until the eighteenth day, when he had a moderately severe hemorrhage from the stomach. After gastric lavage with hot water the bleeding seemed controlled. Twenty-four hours later, however, he began vomiting blood and, in spite of gastric lavage and transfusion of blood, he died, Oct. 14, 1918. Necropsy was held a few hours after the death of the patient, and the stomach was obtained. It showed that the pylorus had healed satisfactorily, but the ulcer had extended to the lesser curvature and involved a blood vessel of considerable size, which was protruding from the ulcer. From this vessel the hemorrhage apparently had come (Fig. 9). Doubtless the ulcer was sutured too tightly, necrosis of the mucosa resulted, and the ulcer spread.

CASE 2.—In the second patient with gastric ulcer (L. B.), an ulcer in a similar location had perforated and a small abscess had formed. A transgastric operation was done, Sept. 27, 1918, and an effort was made to approximate the edges of the ulcer by mattress sutures and a continuous lock stitch within the stomach. The pyloroplasty was then done, and a drainage tube carried down to the abscess anteriorly, without disturbing the adhesions elsewhere. In three days the gastric contents appeared through the drainage tube. The fistula closed in about three weeks, and the patient went home and improved considerably. Four months later, however, he began to have symptoms similar to those before operation. A roentgenographic examination by Dr. A. L. Gray, May 11, 1919, revealed spastic hour-glass contraction about the ulcer, but the pyloric end of the stomach was emptying rapidly and satisfactorily. The patient was again operated on, May 13, 1919. There was no abscess, but the ulcer persisted and was adherent to the liver and pancreas. The ulcer and a portion of the surrounding healthy stomach wall were excised. There were considerable adhesions, but the pylorus appeared to be in a satisfactory condition. The patient is recovering uneventfully.

CASE 3.—In the case of M. L. S., the ulcer was prepyloric, being about 1 inch from the pylorus on the posterior gastric wall near the greater curvature. This ulcer was easily excised through the incision for pyloroplasty (May 6, 1919), an operation which gave excellent exposure. The patient recovered uneventfully and is now complaint-free.

Fig. 10.—A roentgenogram of the stomach of W. J. B., taken two days before operation. There was constant deformity of the duodenal cap. The patient had been suffering for a number of years. The diagnosis was duodenal ulcer.

Fig. 11.—A roentgenogram of the stomach of W. J. B., taken four months after the pyloroplasty. Note the improved tone of the stomach and the ready emptying.

incising constricting bands (Figs. 2, 3 and 4). In addition, the reinforcing with omentum (Fig. 8) adds security to the sutures, prevents adhesions to surrounding tissues, and counteracts the tendency for the pylorus to become fixed high up under the liver, which sometimes occurs after the Heineke-Mikulicz operation.

The postoperative treatment is about the same as that employed for gastro-enterostomy. If there is any vomiting or marked discomfort, the stomach should be promptly washed out under low pressure, not more than a pint of fluid being used at a time. The head of the bed is elevated from 12 to 18 inches, and the patient is given one-half ounce of hot water every hour for the first twenty-four hours and after that 2 ounces of hot water every hour for twenty-four hours. Enemas of 6 ounces of physiologic sodium chlorid solution with one-half ounce of glucose and 1 dram of sodium bicarbonate are given every six hours for the first two days. At the end of forty-eight hours a small amount of liquid nourishment, but not including milk, is commenced and continued until the fourth

Two patients were operated on for stenosis of the pylorus and six for duodenal ulcer. The stenosis was marked with a large amount of connective tissue in both cases. The cicatricial band that formed pockets posteriorly was cut, as shown in Figures 3 and 4, and the mucous membrane sutured transversely to the incision. Of the six duodenal ulcer cases, three had extensive adhesions. In two of these there had been a previous perforation with leakage of the duodenal contents. In one, operation was done about three months after the perforation, and in the other about sixteen months after perforation. Of the remaining three cases two were simple nonadherent duodenal ulcers on the anterior surface of the duodenum and the third was on the upper border of the duodenum.

CASE 4.—All the patients except this one (Mrs. W. W. H.) were examined roentgenographically, and a diagnosis of ulcer was made before operation. In this instance the patient weighed about 230 pounds, and the history seemed to indicate gallbladder trouble. Operation showed the gallbladder thickened, moderately adherent and without stones, but there was an ulcer in the upper border of the duodenum which appeared about to perforate. On account of the fat of the patient and the fact that the duodenal portion of the pyloroplastic incision was placed too near the ulcer, the operation was more difficult in this instance than in any other. She is now complaint free.

This series of cases represents most of the types of ulcer that we have seen, and yet the operation could be done effectively in each case, though in two there was pyloric stenosis and much scar tissue, and in two there had been previous duodenal perforation followed by extensive adhesions.

FINAL RESULTS

Nine of the eleven patients are now living and have been communicated with during the last few weeks. One gastric ulcer patient (L. B.), as described above, has recently been reoperated on for excision of the gastric ulcer, which was not cured by the original operation. He is recovering satisfactorily. The prepyloric ulcer patient, M. L. S. (operated on May 6, 1919), is in excellent condition and is complaint free. Of the two patients with pyloric stenosis, one (F. P. B., operated on May 15, 1919, and the last pyloroplasty that was done) recovered uneventfully till the eighth day after operation, when secondary hemorrhage began, and, in spite of gastric lavage with hot water and transfusion of blood, the patient died the tenth day after operation. Necropsy showed the bleeding came from small vessels in the region where the posterior cicatricial band was cut. The anterior pyloroplasty incision was in excellent condition and the pylorus was wide open. The other (R. D. L., operated on Jan. 22, 1919) has gained 30 pounds and is complaint free. Of the six duodenal ulcer patients (operated on April 4, July 3, July 30, Oct. 4, 1918, Jan. 22, March 31, 1919) four are entirely complaint free. Two express themselves as being greatly improved, but still have minor symptoms, such as occasional gas and gastric discomfort, particularly when imprudent in their diet. Of these two patients one (Miss E. D. H.) had, in addition to a duodenal ulcer, marked ptosis of the stomach and transverse colon, but only the pyloroplasty was done and the appendix removed, no operation being done for the ptosis. If this patient wears an abdominal support she is comfortable and complaint free. She says she is greatly improved (Fig. 13). There is no change in weight. She follows her profession as a trained nurse.

In the other patient (W. W. G.) there had been severe hemorrhage a few days before operation, and at the time of operation there appeared to be acute cholecystitis, the gallbladder being enlarged and congested, and the duodenal ulcer, which had been demonstrated by the roentgen ray previous to operation, was small and nonadherent. The pyloroplasty was done, but, as the gallbladder seemed to be the major trouble at the time, it was drained. This patient now looks well, and feels well most of the time, but has occasional "indigestion" and has to be particular about his diet. He expresses himself as being greatly improved; he works hard, and has gained about 18 pounds in weight since a short time before operation. In these two cases the duodenal ulcer was not the sole and probably not even the chief cause of the symptoms. The symptoms from ptosis seem relieved by an abdominal support, and cholecystitis and drainage probably produced adhesions to which may be attributed the few disagreeable symptoms which the other patient now occasionally suffers.

Five patients were, after the operations, studied with roentgen rays by Dr. A. L. Gray, professor of roentgenology in the Medical College of Virginia. His

Fig. 12.—A roentgenogram of the stomach of Mrs. G. A. H., taken about one year after pyloroplasty. The patient had had a previous duodenal perforation, and there were numerous adhesions. The stomach is emptying satisfactorily.

Fig. 13.—A roentgenogram of the stomach of Miss E. D. H., taken four and one-half months after the pyloroplasty for duodenal ulcer. The patient had marked ptosis. There were no adhesions. The pylorus, as shown, is functioning normally, with a perfect duodenal cap. The pylorus is a little wider than normal.

reports show that the pylorus has returned to its function, though it seems to be somewhat more open than usual. In all of the five patients examined by him, the stomach emptied satisfactorily except in one instance (Miss E. D. H., the patient with ptosis), in which the emptying time, though delayed, is markedly improved over what it was before operation.

Of the five patients in whom the duodenal ulcer (four cases) or stenosis (one case) appeared to be the chief or the only pathologic condition, every one is now complaint free. One has gained 32 pounds, one 30 pounds, one 20 pounds, one 9 pounds, and one (Mrs. W. W. H.) has not gained in weight.

Summing the clinical results, I find there were eleven patients on whom the new pyloroplasty was done, two of whom died. Of this number, three patients had gastric ulcers, with one death, which can hardly be justly attributed to the pyloroplasty; one is complaint free; one had recurrence, which required another oper-

ation, done recently, on the ulcer. There were two patients with pyloric stenosis; one is complaint free, the other died on the tenth day after operation of secondary hemorrhage from the incision in the posterior constricting band. This incision had been made too deep. There were six patients with duodenal ulcer; two, in whom the ulcer was probably not the chief pathologic condition, are greatly improved, but not complaint free; and four, in whom the ulcer was the sole or the chief lesion, are complaint free.

ABSTRACT OF DISCUSSION

ON PAPERS OF DR. BALFOUR AND HORSLEY

DR. RAYMOND P. SULLIVAN, Brooklyn: Dr. Balfour has presented clearly and concisely the interesting subject of recurrent hemorrhage from a gastric or duodenal ulcer. Three points are worthy of emphasis: (1) From the records of such a large clinic, it is evident that gastric hemorrhage is an indication of ulcer in only 25.8 per cent. of gastric ulcer and 20 per cent. of duodenal ulcer cases. Hence, the diagnosis of ulcer depends more especially on the clinical history and roentgen-ray findings. Gastric hemorrhage no longer has the significance formerly attributed to it in the diagnosis of ulcer, but is a very important factor when preceded or followed by definite symptoms. (2) The technique of handling either gastric or duodenal ulcer should be simple and direct. Excision is indicated in gastric ulcer but, when complicated by bleeding, duodenal excision or destruction should be practiced. Three methods of excision may be considered: (a) Suture exclusion or devitalization. This method is rarely practiced today because of its uncertainty in uniformly removing infected tissue, and it has given way to more direct methods. (b) Excision by knife, followed by suture closure, is probably the most universal practice. However, it is apt to be attended by removal of too much tissue predisposing to greater subsequent deformity, or too little, thus favoring recurrence of ulcer, especially if nonabsorbable suture material is used, or retention of early cancer cells. (c) Perforation and destruction by actual cautery is direct and is attended by all the advantages of heat for sterilization; destruction of early cancer cells and control of hemorrhage. Whichever method is used, gastro-enterostomy should follow. In all bleeding duodenal ulcers, ligation of vessels immediately proximate to the ulcer must be considered, although undoubtedly Balfour's method of cautery destruction is a direct attack for destruction of the ulcer area. The third practical lesson to be derived from the paper is that gastro-enterostomy is never indicated because of gastric hemorrhage alone. Nevertheless most cases of gastric hemorrhage are probably surgical due to septic condition of the gallbladder and pancreas or spleen or appendix. I wish to draw attention to the fact that a varicose condition of the veins of the cardia, which frequently accompanies heart or liver disease or in arteriosclerosis, may give rise to gastric hemorrhage, especially if ligation is practiced. In dealing with a perforating adherent bleeding ulcer of the posterior wall of the stomach, the operative procedure must depend on the skill and judgment of the operator. Future risk to the patient for recurrent hemorrhage or development of cancer will depend on the radical removal of the ulcer area. In these cases I have used a combined cautery method after careful knife dissection of the adherent area and have had satisfactory results. The figures presented by Dr. Balfour indicate that a cautery destruction of bleeding ulcers offers a greater protection to the patient against recurrent hemorrhage, and it promises to be a standard technique.

DR. ALFRED A. SIEVENS, Chicago: I think Dr. Balfour has given the medical profession something to think about regarding the value of simple gastro-enterostomy. I hope he will be more successful in persuading the profession on this point than I was five years ago, when I insisted that gastro-enterostomy alone has little value in gastric and duodenal ulcer, and that all ulcer should be excised, if at all possible. At that time I demonstrated methods of excising ulcers, not only in

the upper portion of the stomach but also in the pyloric region and in the duodenum, by reconstructing those portions of the stomach, after excision of the ulcer, by means of fascial transplants reinforced by the free edge of the attached omentum. The use of the omentum not only prevents hemorrhage and leakage, but also furnishes a new collateral blood supply to that portion of the stomach. For the ulcers occurring on the posterior wall of the body of the stomach, which are adherent and cannot be freed, the transgastric incision through the anterior wall of the stomach and the Balfour cauterization method are ideal. As to the question of excision versus cauterization, I do not think one can always tell whether or not the ulcer is malignant, as shown by McCarthy of the Mayo Clinic. It can readily be seen that the Balfour method of plunging the cautery into the center of the ulcer may leave the malignant edges of the ulcer. I therefore believe that wide excision by means of the cautery knife is more effective. I do not believe that gastro-enterostomy after excision of the ulcer is necessary. The purpose of this gastro-enterostomy is to give the stomach a normal, or quicker than normal, emptying time and this can be accomplished by a very simple pyloroplasty. By making an incision one inch in length extending from the pyloric ring back onto the stomach, through the muscularis down to the mucosa, and a half inch incision along the ring at right angles to the first incision on each side, a wedge-shaped piece of the pyloric muscularis can be removed. This allows the mucosa to bulge and this is covered with the free edge of the attached omentum. This simple plastic operation can be done in a few minutes; it destroys the sphincter control and allows the stomach to empty from one and one half to two hours. A fluoroscopic examination of sixteen cases operated by this method showed the emptying time to be from one and one half to two hours.

DR. J. B. BLAKE, Boston: Dr. Horsley has reported his unfavorable as well as his favorable results. If this were not true an operation which suggests the limitation of gastro-enterostomy could not be so well considered. I want to comment on three points in his paper: (1) The parallel which exists between ulcers of the anal sphincter and ulcers of the pyloric sphincter; (2) the function of the pylorus and the importance of maintaining that function, restoring it if possible, and (3) the very great importance of giving this method a fair trial and the necessity of following exactly what Dr. Horsley has pointed out if we are to try his method. So far as I am aware this is the first time that a parallel has been cited between an ulcer of the anal sphincter and ulcer of the pyloric sphincter. At first it seems a little far-fetched but if you will recall what Dr. Horsley pointed out the parallel is closer than one might at first believe. The action of both sphincters is essential to health. One cannot be absolutely normal with the excision or removal of either of the two sphincters. The ulcer in one is as much a source of irritation and spasm as in the other. Dr. Horsley referred to the fact that the stomach is not a passive bag and cannot be drained by a hole in the bottom, that the pylorus is a bit of highly organized physiologic tissue intended to empty the stomach. That it will do so is proved by the fact that any effort of exclusion of the pylorus other than excision has practically never been successful. Even if the pylorus is damaged, it still attempts, and is usually successful in emptying at least part of the stomach. Operations before this time have been of one or two classes. Surgeons have done gastro-enterostomy and excised the pylorus or else they have done one of the exclusion operations which are never successful. I am speaking particularly of cases in which gastro-enterostomy is done and nothing else. Dr. Balfour has shown that in the bleeding ulcer it is not effective, certainly not in ulcers in which bleeding is a prominent feature. If we can substitute an effective operation on the pylorus and restore its function gastro-enterostomy may become unnecessary. No operation can stand, nor should it fall, on the experience or the operative technique of one man alone. Dr. Horsley's operation should be repeated by good operators in all parts of the country. Only then will it be known whether this is going to limit gastro-enterostomy and give something more efficient and more simple.

Dr. Horsley's operation is useful if the ulcer is situated on the anterior surface of the duodenum and if the pyloric ring and antrum are wide. If they are narrow the operation would seem rather difficult. I think a procedure which I have employed a number of times after excision of a duodenal ulcer is more practicable. By taking a tongue-shaped portion of the pyloric antrum and pulling it through the incised ring, the defect left by removal of the ulcer may be corrected. The mucosa and the muscularis are sutured separately and the edges do not have to be inverted. The free edge of the omentum is brought over the operated area. In the ulcers on the lesser curvature demonstrated by Dr. Horsley I do not think that the additional extensive plastic operation for paralyzing the pyloric sphincter is justifiable, when the same effect can be accomplished by cutting a small portion of the pyloric sphincter muscle away, without incising the mucosa.

DR. JOHN T. BOTTOMLEY, Boston: The crux of the matter, of course, is the removal of the ulcer. We must remember, too, that when we excise an ulcer of the stomach or the duodenum we are removing only the end stage of some other pathologic process; hence we should always search for the foci of infection in the gallbladder, appendix, teeth, tonsils, or elsewhere. Even destruction of the ulcer by cantery will not always result in its cure. I have operated on an ulcer of the stomach which had been twice thoroughly cauterized by a most competent surgeon; the symptoms continued until finally resection of the stomach had to be done. No one method is a cure-all in cases of ulcer of the stomach. Destruction by the cantery is not an absolutely certain method of cure but it is a most excellent method and should be tried. I am surprised that so accurate an observer as Dr. Blake failed to remember that Dr. Codman of Boston years ago called attention to the parallelism between the sphincter of the pylorus and the anal sphincter.

DR. GEORGE GOODRICH, Dayton, Ohio: The operation on my duodenal ulcer consisted in ligation of vessels running to the ulcer and a gastro-enterostomy ten days after a very severe hemorrhage. Perhaps I am prejudiced but I am in favor of that operation. Surely the mortality of 1.6 per cent. as compared with two out of eleven would seem to lead us to accept gastro-enterostomy as formerly done. For eight years prior to my hemorrhage I was aware of the possession of a duodenal ulcer but I hesitated in accepting an operation because foreign publications in regard to results were unfavorable and the Rochester Clinic had not published a very full report at that time. Their later report, if I remember correctly, shows that about 98 per cent. of operations for cure of duodenal ulcer by gastro-enterostomy give satisfactory results. It seems to me that with such a statement as that we should be inclined to follow the old method unless something else could be shown to be much superior. So far as my own personal condition is concerned, I am unaware of any operation having been done. The fluoroscope shows everything passing through the new opening and I think some of the faults which have led to disfavor in this operation consisted in making the opening too near the cardiac end, as pointed out by Hartmann of France. It should be made in the motor part of the stomach, the pyloric end. It strikes me that the operation as done at the Rochester Clinic and by most other surgeons is founded on a reasonable and scientific basis and should not be discarded too readily.

DR. JOHN J. GILBRIDE, Philadelphia: Relative to these cases of severe hemorrhage in duodenal ulcer I wish to call attention to an unusual situation of duodenal ulcer occasionally observed. A number of years ago I saw in a Philadelphia hospital a man who was suffering from severe hemorrhage from a duodenal ulcer. This man died before the operation from hemorrhage. At the necropsy on exposure of the upper abdomen there was no sign of lesion in the duodenum. However, on opening the duodenum the ulcer was found in the upper and inner wall. Of course, unless one had considerable confidence in his diagnosis this case surely would have been missed even at operation. With confidence that one is dealing with duodenal ulcer the thing to do would be, of course, to make an incision through the duodenum and expose the ulcer.

In the case referred to a gastro-enterostomy would not have been life saving. Then, again, one would have to be quite certain of the anatomy to deal with the ulcer. It is owing to the risk of occluding the common bile duct. In these cases, in speaking of the ligation of arteries for ulcer situated in other localities, of course, it would be perfectly obvious that it would be necessary in such a case as this one to locate the duodenal branch of the gastroduodenalis artery and then do a gastro-enterostomy after closing the duodenal incision. Whether one would wish to deal with such an ulcer locally would be left to the individual operator. So far as I know such cases are not frequent. And this is the only case of which I have knowledge of an ulcer in this situation.

DR. ALBERT J. OCHSNER, Chicago: I wish to direct attention to a faulty premise which is introduced into every discussion of this subject. In experiments by Cannon and Blake the stomach of the healthy animals had the form needed to do its physiologic work. It is the business of the stomach to store a certain amount of food in one portion, grind it in another portion and deliver it through a normal pylorus. The diseased stomachs which we consider in these discussions have an accumulation of connective tissue and an obstruction in the region of the pylorus which produces an entirely different machine. When you make a gastro-enterostomy you permit the residual decomposed material to pass out of the pouch in the stomach into the duodenum. The conditions are entirely different from those in a normal stomach which could take care of its contents in a normal way. After that has hap-

Fig. 1.—a, gastric pouch; b, duodenum; d, the lowest point in a normal stomach.

Fig. 2.—The position of these points is altered in the dilated stomach; hence the gastro-enterostomy opening is made between a and b.

pened, because there could no longer exist a quantity of residual material and you have given the musculature of the stomach time to resume its physiologic work, you make your observations again and find that the stomach walls are again doing their physiologic function in the old way.

DR. MILLS F. PORTER, Fort Wayne, Ind.: Dr. Balfour said that not a few of these hemorrhages from the stomach and duodenum have their origin in toxic conditions elsewhere than in the stomach. He referred to the gallbladder, the pancreas and other organs as being possible sites of the process giving rise to toxic conditions. All of these points are worthy of emphasis. A further fact to which I would call attention is that given an individual who has, or has had, an ulcer of the stomach and has now the remains of it with the hemorrhage, it does not follow that the hemorrhage comes because of the ulcer. A patient came to me to be relieved of severe hemorrhage supposed to be due to a duodenal ulcer first diagnosed by me about fifteen years before. I did a posterior gastro-enterostomy and found a small insignificant scar on the anterior aspect of the duodenum within half an inch of the pylorus. For a few days he had a rather stormy time, apparently from kidney insufficiency, but after that he made a prompt recovery. He went along nicely for a time and then had a sudden hemorrhage. He was referred to another clinic and the pyloric portion of his stomach was removed. The man made another recovery and came back home. He had another collapse and another hemorrhage, and this has been

repeated several times. My point is that my diagnosis was correct. He did have a duodenal ulcer, but he was bleeding because he had an arterial condition largely the result of a chronic contracted kidney which I overlooked. I made a mistake when I did the operation on his stomach. My friend who operated afterward made another mistake. There is some way, perhaps, by which we might arrive at the correct conclusion in these cases. If there is I would like to know how to do it.

DR. WILLIAM J. MAYO, Rochester, Minn.: I am very much interested in the operation proposed by Dr. Horsley, because the last word has not been said concerning ulcers of the stomach, and the best procedures for getting rid of them. I think, however, that we should ask Dr. Horsley to come before us next year when he will have had an opportunity to perfect his technique. As Dr. Blake says, in order to test the method his technique should be followed exactly. I must say that the two deaths in his eleven cases made me a bit conservative, although, as Dr. Horsley has pointed out, both deaths were due to accidental causes that might be avoided in the future. I think there is opportunity for such an operation and I hope that Dr. Horsley will carry it to its logical conclusion. The old question of cure as the result of operation comes up. Let us bear in mind that ulcers of the stomach and duodenum as they are seen by the surgeon are chronic diseases that have been treated medically for years. I have been asked, "When does a chronic ulcer of the stomach or duodenum become surgical?" For various reasons the answer has been: "After nine complete and perfect medical cures." With regard to the question of failure to cure surgically, I would put it down as a Hibernianism, that the first cause of failure is in doing an operation—gastro-enterostomy usually—on a patient who has no ulcer. We have records of having cut off more than 300 unnecessary gastro-enterostomies, closing the stomach and jejunum. These operations were done in cases in which there was no evidence either in the history or the condition found at the second operation that ulcer had existed. Fourteen of these were my own early cases. The most common cause of failure of operation to cure, when an ulcer really exists, is the use of silk as suture material which, in a certain percentage of cases, leads to secondary ulcer in the suture line. A very large majority of gastrojejunal ulcers (so-called jejunal) are due to ulcerations around silk sutures which cause the same symptoms as the original ulcer. In the course of time, in many instances, healing takes place as the silk passes out. Such cases are mostly responsible for the opinion that medical treatment is necessary after operation. In 1914 Dr. Charles H. Mayo stopped using silk. We all have now adopted catgut, and in more than 4,000 gastro-intestinal anastomoses of various kinds in the clinic there has not been a single instance in which catgut has failed to be satisfactory. Some of the gastrojejunal ulcers become chronic or complicated fistulas form between the colon, stomach, and jejunum. Regarding the excision by cautery and excision by knife: If an ulcer which is cancerous or is beginning to be cancerous is excised with the knife, cancerous cells may be grafted on the edges of the cut wall of the stomach. I have known this to happen so often that I am now afraid to cut into a cancer to take out a piece for microscopic examination, unless I remove the growth at once. I could report such unfortunate occurrences. We can say that there are three periods in the life of a normal cell, growth, function and senility. The malignant cell has but two periods, growth and senility; it has no period of function, but unfortunately it undergoes most active cell division in the embryonic stage. It has been shown that cancer cells are five times as vulnerable as the normal cells. If the cautery excision is used, cell division will be stopped at a distance beyond the actual excision.

DR. CHARLES A. L. REED, Cincinnati: When I heard Dr. Mayo say that the last word on this subject had not yet been spoken I was hopeful that he would speak it. Having listened to him I am still convinced that the last word has not been spoken; and I am quite sure that after I shall have concluded my remarks you, in turn, will say that the last word has not been spoken. The point to which I want to call attention is one which is of enormous importance in the pathology of this

condition. Both the essayists called attention to the fact that in certain cases in which hemorrhage followed operation pre-existing ptosis had remained uncorrected. I wish to call attention to the fact which has not been mentioned in either one of the papers that in every one of these cases in which this operation was done there was found the condition of extreme visceral cyanosis, a dammed back venous circulation, the primary effect of which is a gastric catarrh. With a general visceroptosis there will be, first, a general venous engorgement and, next, a resulting catarrhal condition of the duodenum and other portions of the alimentary tract, noticeably the colon. Then, as the back pressure in the veins increases to a certain point and the carbon dioxide content of the veins reaches a certain point, molecular death ensues in the follicles and the process of progressive ulceration is inaugurated. In the majority of these instances I am convinced, logically, although I am not able actually to demonstrate it, that these hemorrhages, preoperative and postoperative, are derived in whole or in part from the venous side of the circulation. Therefore, if you have a persistence of the ptosis which causes the venous engorgement and a persistence of the venous engorgement which causes the hemorrhage, you necessarily have a recurrence of the hemorrhage and a persistence of the ulcer. You have such general persistence of both these conditions simply because you have not eliminated the cause, or, in other words, the underlying pathologic factor in the venous circulation. I have been convinced of the importance of this angle of view by repeated experiences, and I find that in so far as I control and restore the venous circulation my recoveries are permanent, and that in so far as I fail to do this, my recoveries are uncertain, to say the least.

DR. DONALD C. BALFOUR, Rochester, Minn.: Ligation of vessels should always be considered when hemorrhage has occurred. Dr. Strauss makes a plea for excision alone in gastric ulcer. We have so frequently seen patients who have failed to secure relief from symptoms by excision alone, that we now always combine gastro-enterostomy with excision. Regarding excision by the knife or by cautery, Dr. W. J. Mayo has left nothing to be said, but I think the fact should be emphasized that experience with the cautery in malignancy shows that the cautery effectually destroys any cancer cells which may be in the ulcer base, and that knife excision of an ulcer which has undergone early malignant change is always associated with the danger of cancer cells grafting. The danger is avoided in cautery excision. In regard to the best operation in benign lesions of stomach and duodenum, any effort to establish a certain operation as a routine operation in such lesions is inadvisable, and it is only by making use of the various types of operations which have been devised that the surgeon will secure the best results.

DR. J. SHELTON HORSLEY, Richmond, Va.: The first death was due to hemorrhage from an ulcer in the cardiac portion of the posterior wall of the stomach. In the excision of this ulcer I did an intragastric incision and tied the mattress sutures too tightly in the mucosa of the stomach where the ulcer was excised. The second death was due to the fact that I cut too deeply. Here I am quite sure there would have been no occasion for secondary hemorrhage had I confined the incision to the scar tissue. It is hardly fair to condemn an operation because of two deaths of that character or to compare the mortality of a new procedure with that of a standardized operation such as gastro-enterostomy. Excluding stenosis and gastric ulcer, my mortality in duodenal ulcer is *nil*. I am doing the operation only because I believe I can get better results for my patients by this procedure. In treating ulcer in and it is essential, after getting rid of the pathology, to obtain physiologic rest by eliminating or diminishing the function of the sphincter. In this operation we cut the pyloric end of the stomach for the same reason. Excision of the ulcer alone is not effectual. We incise at the region of greatest contraction and so give physiologic rest. I have used catgut throughout, following the suggestion of the Mayo Clinic. Dr. Ochsner said the stomachs in which operation for ulcer is done are dilated. This is because of obstruction or pyloric spasm, and if you remove the obstruction as advocated in this

pyloroplasty you decrease the burden of the stomach in emptying its contents and it returns to the physiologic norm. The facts are that in this pyloroplasty the pathology is excised or corrected, the tissues are put at physiologic rest during healing which is a first principle in all surgery, and the stomach is returned to its normal function. In gastro-enterostomy, even if one closes the pylorus, it opens and a portion of the food goes over the ulcer, so but little rest is afforded; the ulcer is often not removed; and the stomach function is anything but physiologic.

THE PHYSIOLOGY OF SNEEZING*

ALBERT P. BRUBAKER, M.D.
PHILADELPHIA

Sneezing may be defined as a spasmodic expiration preceded by one or more spasmodic inspirations. The expiration is momentarily opposed by the closure of the nasopharynx and a more or less complete closure of the mouth. With the onset of the expiration there is a rapid rise of intrapulmonic pressure which, when a certain value is attained, suddenly forces open the nasopharyngeal partition. In consequence, a blast of air is driven into and through the nasal chambers; at the same time, however, the mouth, not infrequently, is partially opened, thus permitting a portion of the blast to be driven through the buccal orifice. The object of the sneezing spasm is the dislodgment of mucus or other fluid from the surface of the nasal mucous membrane.

The act of sneezing is, in its entirety, quite complex, and may be subdivided for convenience of presentation into two phases, a nasal and a respiratory, both of which are reflex in character and involve two different reflex mechanisms, a nasal and a respiratory. Each mechanism consists of afferent nerves, a central mechanism, efferent nerves and responsive organs.

THE RESPIRATORY PHASE

As the effective portion of the sneeze is the respiratory, it will be conducive to clearness if this is considered first.

The primary activity in this reflex is a deep inspiration or an enlargement of the thorax and lungs, which has as a result the inhalation and temporary storage of a large volume of air, a condition essential to the satisfactory accomplishment of the object of the sneeze. The inspiration is an active process and is accomplished by the simultaneous and coordinate contraction of various groups of muscles, among which, as representatives, may be mentioned the posterior crico-arytenoids, the diaphragm and the external intercostals. The coordinate action of the three groups of muscles implies the coordinate activity of three groups of nerve centers and their related nerves; thus, the activity of the posterior crico-arytenoids is called forth by the discharge of energy from the laryngeal center in the medulla oblongata, and transmitted by efferent fibers in the trunk of the vagus and their continuation in the inferior or recurrent laryngeal; the activity of the diaphragm and the external intercostals is called forth by the discharge of energy from the phrenic and intercostal centers in the cervical and thoracic segments of the spinal cord, respectively, and transmitted by the phrenic and intercostal nerves.

The coordinate contraction of the different inspiratory muscles implies a practically simultaneous discharge of nerve energy from each of the foregoing nerve centers; and this in turn necessitates the existence in the central nerve system of a single group of cells from which nerve impulses are discharged and transmitted by its axonic processes to the laryngeal, phrenic and intercostal nerve centers in the medulla oblongata and the spinal cord, and by which they in turn are excited to and coordinated in their activity. To this group of cells the term "inspiratory center" has been given.

Though the activity of the inspiratory center is normally regulated by nerve impulses ascending the vagus nerves from the lungs, nevertheless it is capable of stimulation in a more or less abnormal manner by the arrival of nerve impulses through other afferent nerves coming from different regions of the body.

The secondary activity in this reflex is a forcible expiration, or a diminution in the size of the thorax and the lungs, which has as a result a compression and expulsion of the previously stored volume of air. Though expiration is normally a passive process and accomplished by the recoil of the elastic forces of the thorax only, under the conditions characteristic of sneezing, these forces are reinforced by the coordinate contraction of various groups of muscles, among which, as representatives, may be mentioned the internal intercostals and the abdominal muscles.

The coordinate action of these groups of muscles likewise implies the coordinate activity of groups of nerve centers and their related nerves. Thus, the activity of the internal intercostals is called forth by the discharge of energy from nerve centers in the thoracic segments of the spinal cord and is transmitted by the intercostal nerves; the activity of the abdominal muscles is called forth by nerve energy discharged from the lower thoracic, and perhaps upper lumbar, segments, and is transmitted by the lower thoracic and the iliohypogastric nerves.

The coordinate contraction of the expiratory muscles implies a practically simultaneous discharge of nerve energy from each of the foregoing nerve centers; and this, in turn, necessitates the existence in the central nerve system of a single group of cells from which nerve impulses are discharged and transmitted by its axonic processes to the intercostal centers in the spinal cord, and by which they in turn are excited to and coordinated in their activity. To this group of cells the term "expiratory center" has been given.

As to the manner in which the expiratory center is stimulated, if at all, under normal conditions of respiration, there is not much definite information available. But as a forced expiration always involves a volitional effort or a discharge and transmission of nerve energy from the cerebrum to the expiratory center, it may be conceived that under the conditions of the respiratory apparatus peculiar to sneezing, the expiratory center is aroused to activity by the descent of nerve impulses from the cerebrum.

Just preceding and conditioning the forcible expiratory effort, the respiratory passage is shut off from the nasal cavities by a partition formed by the elevation of the palate, the advance of the posterior half arches, and the contraction of the superior constrictor of the pharynx. This cooperative muscle contraction results from the discharge of energy from the cells of origin of the spinal accessory nerves.

* Read before the Section on Laryngology, Otolaryngology and Rhinology at the Seventieth Annual Session of the American Medical Association, Atlantic City, N. J., June, 1919.

At this moment the intrapulmonic air is compressed on all sides by the descent of the ribs, the result of the contraction of the internal intercostal muscles, and by the upward movement of the abdominal viscera, the result of the contraction of the abdominal muscles. With the rise of the intrapulmonic pressure, there comes a moment when the nasopharyngeal partition is forcibly separated, and the air is driven into and through the nasal chambers with a more or less complete dislodgment of the mucus.

The afferent portion of the nerve mechanism, by which the inspiratory reflex is occasioned, consists of fibers of the trigeminal nerve, the peripheral terminations of which are distributed to the nasal mucous membrane, and the central terminations related histologically and physiologically to the inspiratory center.

The stimulus adequate to the excitation of these peripheral nerve endings is a dilatation of nasal blood vessels and the discharge of clear, slightly viscid secretion, perhaps specific in character, from the glands embedded in some portion of the nasal mucous membrane. When this secretion is discharged and begins to trickle over the terminals of the nerve endings in certain regions, nerve impulses are developed which, transmitted to the inspiratory center, stimulate it and cause it suddenly to discharge energy to the spinal inspiratory centers and muscles. With this, the effective portion of the sneezing mechanism is excited and coordinated in activity.

Coincidentally with the stimulation of the afferent nerve fibers of this reflex mechanism, there occurs simultaneously a stimulation of purely sensory nerves. The nerve impulses developed in them are transmitted to sensory areas in the cortex of the cerebrum, where they evoke sensations of a peculiar trickling or quivering character which contribute much to the pleasure of the sneeze, and at the same time lead to various muscle reactions and sounds of a more or less pronounced character.

THE NASAL PHASE

As stated in a previous paragraph, the stimulus adequate to the excitation of the sneezing mechanism is the production and discharge of a secretion from glands in the nasal mucous membrane. The production of this secretion is also a reflex act and involves a nerve mechanism consisting of afferent nerves, central cells, efferent nerves and their related responsive organs, glands and blood vessels. Collectively their physiologic action constitutes the nasal phase of sneezing.

The production of the stimulating secretion requires the cooperation of blood vessels and gland epithelium, both of which require for the manifestation of their activity the stimulating influence of nerve energy originating in the central nerve system and transmitted to them by the afferent nerves of the reflex mechanism.

The nerves distributed to these structures belong to the autonomic system, and therefore consist of two consecutively arranged and histologically related neurons known as preganglionic and postganglionic.

In a consideration of this mechanism it will be convenient to consider the postganglionic neurons first. The cell bodies of these neurons are found in, and compose in large part, the sphenopalatine ganglion. From these cells axonic processes pass forward to become histologically related to the walls of the blood vessels and the epithelium of the nasal glands, from

which it may be inferred that the sphenopalatine cells are related to vasomotor and secretomotor phenomena. The sphenopalatine cells, however, do not possess spontaneity of action, but require for their excitation the arrival of nerve energy, originating in cells in the central nerve system and transmitted to them by their preganglionic axons. These cells, which constitute the central part of this reflex mechanism, are located in the gray matter beneath the floor of the fourth ventricle. The axonic processes to which they give rise pass forward and emerge from the medulla in the nerve of Wrisberg, of which they constitute a large part; they then pass into the sheath of the facial nerve; after a very short course they leave the facial nerve at the genu, and after that become the great petrosal nerve, the peripheral terminations of which arborize around the cells of the sphenopalatine ganglion.

There is thus established a pathway between the central nerve system and these local peripheral organs along which nerve impulses pass from the center to the periphery. That this is the case is shown by the results of experimentation; thus, if the great petrosal nerve in one of the higher mammals is divided and its peripheral end stimulated with induced electric currents, there promptly occurs a dilatation of the nasal blood vessels and a secretion from the nasal glands. Stimulation of the sphenopalatine ganglion has a similar result. From these facts it may be inferred that the nerve fibers composing the great petrosal nerve, as well as the cells from which they arise, are divisible into two groups, namely, vasodilator and secretomotor. Any stimulation, therefore, of the central cells will be followed by vascular engorgement and the discharge of mucus.

The afferent portion of the mechanism is widely distributed, though it may be said to consist mainly of (1) cutaneous nerves, (2) nasal branches of the trigeminal, (3) visceral afferent nerves, and (4) nerves descending from the cerebrum.

The stimulation of certain cutaneous nerves, as is frequently the case when they are suddenly exposed to a low temperature or cooled by currents of air, will cause a dilatation of the nasal blood vessels and a discharge of mucus, which in a short time will stimulate afferent nerve endings and occasion a series of reflex spasmodic sneezes. This stimulation holds true for the ankle, neck and head areas of the skin. The impulses thus peripherally generated are transmitted to the central vasodilator and secretomotor cells, and excite them to activity.

Stimulation of the trigeminal nerve endings, chiefly in the nose, perhaps elsewhere, will cause the same vascular and secretory conditions, as is well known. The stimuli capable of exciting these nerve endings may be mechanical and chemical, as well as organic, emanations, of a more or less unknown nature, from animals and plants. Here, again, the primary effect of these stimuli is the production of the nasal mucus.

Stimulation of other sensor nerve endings, of the glossopharyngeal, the vagus, etc., has been observed to cause the same nasal phenomena, followed by more or less pronounced sneezing.

PSYCHIC STIMULATION

Stimulation of vasomotor, secretomotor and visceromotor centers in the medulla oblongata and spinal cord, by nerve impulses descending from the cerebrum in consequence of psychic states of an affective or

emotional character, is a well attested fact. It is only necessary to recall the effects of psychic states on the nerve centers regulating the vascular and secretory phenomena preceding the discharge of saliva and gastric juice; and on the nerve centers regulating the vasodilator and the secretomotor phenomena of the sexual organs. Paralleling these effects are the effects of the psychic states on the vasodilator and secretomotor phenomena of the nasal organs. It has, moreover, been frequently observed that the nasal and sexual phenomena often coexist, the two not standing, however, in the relation of cause and effect but as results of the same psychic state.

PATHOLOGIC CONDITIONS

In this presentation the attention has been limited to the consideration of the normal or physiologic condition. This, if properly conceived, may assist in the interpretation of pathologic conditions. It is quite apparent that pathologic conditions might arise from an alteration in the way of an increase in the irritability of the afferent portion of the mechanism of the nasal phase of the reflex. Local pathologic states frequently so exalt the irritability of the nerve endings that a slight additional stimulation develops a greater number of nerve impulses than would otherwise be the case. As a result, the associated central cells are more profoundly stimulated and cause by their greater discharge of energy more pronounced peripheral effects. It not infrequently happens, also, that the nerve impulses thus developed are so numerous that they overflow their customary channels and stimulate vasodilator, secretomotor and visceromotor centers in different levels of the medulla oblongata and the spinal cord, causing, in addition, the development of pathologic phenomena in the respiratory, the circulatory and other organs as well. Instability of the central mechanism, either in itself or as an expression of a more general nerve cell instability, the result of heredity or of dietetic or sexual excesses or other conditions, may lead to similar results.

NASAL HYDRORRHEA*

JOHN A. THOMPSON, M.D.
CINCINNATI

The rare disease, called by Bosworth nasal hydrorrhea, by others rhinodema or edematous rhinitis, has been given little attention in the literature of our specialty. There is no description of it in the books written by Ingalls, Coakley, Watson Williams, Packard, G yson, Gile or Reik. Gleason writes of it very briefly. In the last edition of his book, he describes two types, the inflammatory and the noninflammatory. Coolidge writes of it as would an author who had had no opportunity to study cases. The same statement would apply to Ballenger's work. Price Brown describes one case, Sharley's description is very brief. D. Braden Kyle, in the early edition of his book, says he can find authentic records of only twenty-seven cases. Grayson¹ describes it, although his title is, "The Nasal Phenomena of Neurasthenia." Phillips gives less than

half a page to a description of this disease, and much of that space is taken up with the chemistry of the discharge. There are numerous references to it in the *Index Medicus*, but careful reading of the articles reveals that everything from hay-fever to the nervous degeneration of advanced diabetes has been described as nasal hydrorrhea.

Because so little attention has been given it, cases are being overlooked by good men, and this is sufficient reason for presenting the topic to this section.

We do not know the cause of the disease. Curtis has found it associated with sexual perversion in young adults, but this is not a factor in many cases. I can find no record of postmortem examinations of the pathologic condition. The cases described by Bosworth, in which postmortems were performed, were undoubtedly unrecognized cases of sinus suppuration. Lacking the exact knowledge of its pathology, we can best define nasal hydrorrhea as an obscure nervous disease, the chief symptoms of which are nasal. There is some relation between this disease and that very obscure nervous affliction known as angioneurotic edema. The phenomena of the two diseases are similar. In three of my patients, both conditions were present. The disease is most common among younger men and women of sedentary habits. There are no known external exciting causes such as produce hay-fever, or as in the edema produced in certain persons by the emanations of horses, cats or other animals. The local pathologic condition is a dropsy. The connective tissue interspaces of the turbinated bodies are filled with serum. If surgical intervention is necessary in the typical cases, the fluid discharged is only slightly blood tinged instead of showing evidence of the free hemorrhage resulting when a turbinate is injured.

The characteristic symptoms of nasal hydrorrhea are a sense of extreme irritation in the nose, followed by sneezing and a very profuse watery discharge from both nostrils. The discharge varies in amount from an ounce to a half pint in twenty-four hours. The fluid is alkaline and contains small amounts of sodium chlorid and traces of phosphates. The presence of mucin differentiates it from the cerebrospinal fluid discharged from the nose after injuries.

In some patients, the discharge persists throughout the day. In others it is periodical, flowing for hours and then ceasing until the next day. Cold winds, dampness and dust aggravate the symptoms. After some months of this annoying flow, polypi appear. Their removal has only a mechanical effect in opening the nostril, as the other symptoms are not modified. They soon recur.

A direct examination of the nose reveals that the mucosa is pale bluish, sometimes translucent. The swollen turbinates entirely fill the nasal cavity. Persistent rubbing with cotton pledgets soaked with an epinephrin and cocaine solution will sometimes enable one to shrink the tissues temporarily until it can be seen that no hypertrophy is present. Usually the entire length of the turbinated body is affected. In some cases the anterior portion, in others the posterior portion is more edematous. The disease may begin at any season of the year, and last for months or years.

We have a distinct clinical picture of a rare disease, the symptoms of which resemble hay-fever, but which is not hay-fever. One reason for the opinion that the disease is nervous in its origin and that the nasal symptoms are significant only of lesions in the nerve

centers is the marked mental depression, amounting almost to melancholia, from which these patients suffer. Another reason is, I think, from my experience in the cases I have treated, that any unusual mental or emotional strain greatly aggravates the nasal symptoms. A final reason for the belief in the essentially nervous origin of the disease is the absolute failure of local treatment to give relief, and the success of tonic and hygienic measures. There is no evidence to show that the disease is one of anaphylaxis, or one due to disorders of the endocrine glands.

REPORT OF CASES

CASE 1.—My first patient, treated thirty-three years ago, was a merchant, aged 30. While in his store in the mornings, between 9 and 10 o'clock, he would feel a sudden occlusion of the nostrils, and before he could get a handkerchief out of his pocket the serum would be dripping from his nose. The flow would continue for about six hours; then he would be comfortable until the next morning, when it would recur. During the attack the lower eyelids would be black from venous congestion. These daily periods of suffering would persist for six weeks, and then he would have several months of ease, only to suffer again in the former way if worried by business responsibilities or if overworked. He finally made a complete recovery. Neither polypi nor sinus suppuration developed in this case. He is still living and in good health.

CASE 2.—Another typical case of nasal hydrorrhea was that of a maiden lady, aged 40. She had suffered for months before I saw her. Polypi had already developed in this case. Their removal gave little relief, as the edematous turbinates promptly filled the space left by their removal. The nasal stenosis and constant free discharge greatly interfered with her rest, and her general condition was bad. Under tonic and hygienic treatment, she improved for a time. She was passing through the menopause, and at every recurrence of menstruation, usually once in three months, there was a return of the acute nasal distress. This exacerbation would last for varying periods, and then would come an interval of comfort. Local treatment never had any notable effect in relieving her. Something had to be done to the nose for the effect in relieving the woman's mental depression, but all the real good accomplished was effected by the use of hygienic measures. Ten years after beginning treatment, she still has occasional attacks.

CASE 3.—Another patient, a physician's wife, had been treated for several months by one of my colleagues for hypertrophic rhinitis. There was no evidence of inflammation in the nose, and the very profuse discharge revealed the true nature of the case. Sprays of a weak solution of epinephrin gave some relief to his patient. Vigorous outdoor exercise and cold douches to the spine effected a cure.

CASE 4.—A case with an interesting sequel is that of E. T. C., an attorney, who was under observation for three years. He also was treated for hypertrophic rhinitis before I saw him. There were polypi present in this case, when I first examined him, and the anterior end of the left middle turbinate bone was dead. Removal of the polyp and of the diseased bone gave some relief, but I was never able to prevent recurring attacks. The patient was a man of good habits and otherwise healthy. His manner of living was in accord with the best teachings of modern medicine, except that he was overworked. Excessive mental exertion seemed to be the most common cause of an acute attack. Sometimes the preparation of an important case for trial would bring on the acute condition, and the nasal obstruction and the loss of sleep would so impair his mental progress that he would be unable to try the case.

At other times the strain of a court trial would be the exciting factor, and he would come to my office with open mouth, serum dripping from his nose, eyes red from loss of sleep, throat congested from the mouth breathing and, altogether, would present a pitiable object of human suffering. Even in his quiescent periods, the membrane in the nose was

always pale and bluish. In December, 1910, while visiting in Chicago, he had an attack of angioneurotic edema involving the whole face except the nose. He was confined to his bed for a week with this illness. Since that time there has been no recurrence of edema. The occurrence of an attack of angioneurotic edema in a typical case is another evidence of the essentially nervous nature of the disease. He later developed a frontal sinusitis and was operated on by one of my colleagues.

CASE 5.—The nervous disturbances attending the first pregnancy in a young married woman seemed to be the exciting factor in this case. So extreme was the edema that the dropsical anterior ends of the inferior turbinates could be seen at the nostrils. No amount of epinephrin and cocaine would shrink the tissues so that any air could be inhaled through the nostrils. The patient could not lie down to sleep without causing dyspnea. Her mental condition was that of beginning melancholia. Prompt relief was imperative; so I resorted to operation rather than wait for the slower results of hygienic treatment. The anterior ends of the inferior and middle turbinates in the right nostril were removed. A few days later the anterior end of the inferior turbinate in the left nostril was snared off. This gave sufficient breathing room to let her lie down and, with tonic treatment, improvement was rapid. This patient had a slight recurrence in the early weeks of a second pregnancy.

CASE 6.—In the case of a young man seen in December, 1918, the nasal dropsy extended to the palate, producing suffocative symptoms. He is syphilitic, and the anemia due to that disease aggravates the attacks.

DIFFERENTIAL DIAGNOSIS

The differential diagnosis of nasal hydrorrhea must be made from hay-fever and from the escape of cerebrospinal fluid from the nose. Attacks of nasal hydrorrhea occur at any season of the year and are not excited by pollen. The discharge of nasal hydrorrhea contains mucin and no sugar. The cerebrospinal fluid contains no mucin and precipitates Fehling's solution.

CASE 7.—One unusual case I saw in 1910 could easily have been mistaken for unilateral hydrorrhea. All the partition cell walls in the right ethmoid had been destroyed. The cavity was lined with a membrane secreting a clear fluid. There was a small opening in the cavity above the middle turbinate. When the patient stooped, a half ounce of fluid would gush from the nostril. Free opening of the cystlike cavity cured her.

TREATMENT

In the mild cases, sprays of epinephrin solution, one part of epinephrin to 7,000 of saturated solution of boric acid, have sometimes given relief. In the severer cases, the epinephrin preparations do not secure even temporary contraction of the vessels in the turbinated bodies. Cocain must be applied only by the physician himself, and with extreme caution. The patient's mental condition is such that he will use anything to open the occluded nostrils and check the discharge, and the drug habit is quickly formed. A spray solution that has given a remarkably prompt relief in acute inflammation of the nose would seem to be useful in nasal hydrorrhea. The formula is given herewith:

FORMULA OF SPRAY SOLUTION*

Atropin (alkaloid)	gr. .58
Epinephrin	gr. .1
Menthol	gr. .1
Camphor	gr. .1
Oil of sweet almond	15 i
Liquid petrolatum	15 vi

Mix and dissolve.

*As this solution is one the druggist cannot make without special instructions, the method of dissolving the epinephrin in oil is given. Triturate the menthol, camphor, epinephrin and atropin (alkaloid) in a mortar until they become a uniform preparation for some time after liquefaction "until the mortar runs." Add the mixed oil of sweet almonds and liquid petrolatum very slowly, with constant stirring. Bottle and let stand for twenty-four hours with occasional shaking. Filter through a dry funnel into a dry bottle, and the preparation is ready for use.

Operative measures, except for the removal of polyp, should be used with extreme caution. A real physician does not amputate a dropsical leg, but seeks the cause of the dropsy and treats the causal condition. A dropsical turbinate should also be treated conservatively, and the cure of the disease should be our aim.

As most of these patients are women or men of sedentary habits, active exercise in the open air is the first essential treatment. If this exercise is vigorous enough to produce free perspiration, the result will be much better.

The exercise should be followed by a hot, cleansing shower bath, ending with a cold shower down the spine. In some very delicate women, massage must be given for a time to tone up the flabby muscles so that exercise can be taken. The bowels and kidneys must be kept active with salines and natural aperient waters. If the open air exercise is taken, the appetite and nutrition will be restored without medication. Nerve tonics help in the early cases.

The only positive claim for a cure by medication which I can find in medical literature is that of Lake. He gives from 30 to 40 grains of calcium lactate daily.

RECAPITULATION

There is a rare disease with edema of the turbinated bodies as its most characteristic feature. This edema is not secondary to inflammations in the nose or accessory sinuses. The degenerative changes in the nasal tissues are result and not a cause of edema.

The disease is not caused by climatic conditions or seasonal changes. It is chronic in its course, often lasting, with occasional intermissions, for years.

The nasal edema is probably a symptom of a nervous disease.

ASTHMA AS A NASAL REFLEX *

GREENFIELD SLUDER, M.D.

ST. LOUIS

The consideration of asthma as a reflex from nasal disease has been a matter of interest to all of us for many years, primarily because of clinical results that are sometimes obtained by its treatment, and also because of the scientific interest we have in its problems.

This chapter of medicine was an enigma to me until the past few years: none of the observations published seemed to explain the mechanism of the disease.¹ Now, the question seems to me to present possibilities, if not of solution, certainly of interesting speculation. These ideas came to me in the course of my observations on the "lower half" headache² produced in sphenoidal and nasal ganglion lesions.

To my mind, the explanation of the pain produced from the nasal (sphenopalatine-Meckel's) ganglion, necessitates the assumption of functions on the part of the sympathetic nervous system which cannot be proved, according to the conclusions of the foremost

men who have worked in this field—Langley,³ Gaskell,⁴ Ranson,⁵ and others.⁶

The question of whether or not asthma is a clinical entity is much too large to be considered in such a presentation as this, as is also the question of the sympathetic nervous system, except for the special points I want to mention.

In my explanation of the "lower-half" headache, it must be assumed that in man the sympathetic nervous system has the power of transmitting, under pathologic conditions, afferent pain impulses from the nasal ganglion into the neck and shoulder, etc., though the entire argument of anatomists and physiologists at present is against this assumption. Some of the writers speak of sensory fibers in the sympathetic nervous system. These are stated definitely⁷ to be dendrites of neurons, which have their cell-bodies in the posterior root ganglia; and it is asserted that they are transmitted by the sympathetic trunk merely as a pathway. Buch⁸ seems to have proved that the sympathetic nervous system, in some way, is capable of transmitting afferent pain impulses.

In my explanation of asthma as a nasal reflex, it must be assumed that the sympathetic nervous system is also capable of transmitting afferent impulses which are not painful sensory ones, because many patients with nasal asthma do not have any pain of any kind. If this be true, the explanation of asthma as a nasal reflex becomes possible.

It is known that the sympathetic nervous system in the nose is derived from the nasal ganglion. This receives its sympathetic nerve supply from the vidian nerve; the great deep petrosal; the carotid plexus; the superior cervical ganglion, etc. If, then, the sympathetic nervous system has the power of transmitting afferent impulses, the impulse may readily be traced from the inflamed nose by way of the nasal ganglion, the vidian nerve, the carotid plexus, to the sympathetic trunk in the neck to the lower cervical and first thoracic ganglia, which are often united, and frequently spoken of as the stellate ganglion.

Through this ganglion pass the fibers from the second, third and fourth thoracic nerves that turn downward, being accelerator fibers for the heart, and vasomotor fibers for the lung.

In what way the impulse is transferred from the cervical sympathetic to the cardio-accelerator and pulmonary vasomotor fibers is not to be speculated on at present; nor is it possible to speculate as to which ganglion serves as the relay or transfer station for the impulse. Langley³ states that the cardio-accelerator fibers arise in the second, third and fourth thoracic nerves, and pass through or to, the first thoracic or inferior cervical ganglion, thence to the heart. Ranson⁵ states that these fibers go to the inferior middle and superior cervical ganglia, and thence to the heart. Langley states that the vasomotor fibers for the

3. Ranson: An Introduction to a Series of Studies on the Sympathetic Nervous System, J. Comp. Neurol., 29: 205, 1916.

4. The literature of the sympathetic (visceral) nervous system is somewhat difficult to read because of the nomenclature, which is still in considerable confusion. There are three separate nomenclatures, and there are also three types of observers, namely, the anatomists, the physiologists and the neurologists. I use the term sympathetic in the older sense, as including the entire involuntary nervous system.

* Read before the Section on Laryngology, Otolaryngology and Rhinology at the Seventeenth Annual Session of the American Medical Association, Atlantic City, N. J., June, 1919.

1. One of the best statements of the questions concerned in it is by H. L. Lack: Diseases of the Nose, New York, Longmans, Green & Co., 1905. He, too, is of the opinion that nothing in the literature bears on the nasal mechanism of the disease.

2. "Lower-half" headache is a convenient designation for pain in and about the eye, the maxilla and the teeth, passing back to the temple, ear, mastoid, occiput, neck and shoulder. For further details see Sluder, Greenfield: Headaches and Eye Disorders of Nasal Origin, St. Louis, Mosby & Company, 1918.

lung arise in the third to seventh thoracic nerves, and pass up to the inferior cervical ganglion, and then to the lung. Ranson does not mention the pathway of these fibers. It would seem that the relay station for the asthma reflex must be in the cervical sympathetic ganglions, whereas the pain in the neck and shoulder would seem to be relayed in the posterior root ganglions; and it would appear that the asthma impulse must be inhibitory to the vasomotor fibers.

EXPERIMENTAL AND CLINICAL DATA

In a perusal of the literature of the sympathetic nervous system, one is impressed by several difficulties in utilizing for clinical purposes the information found. One fact appears very soon, to wit, almost none of the observations have been made on man. Another is that the animals studied vary considerably, giving rise to the feeling that man is probably different from any of the lower animals. Kuntz⁹ observed the development of the cervical sympathetic ganglions of the fish, amphibia, turtle, chick and pig. He found that the nasal ganglion developed from cells which had their origins in the geniculate and gasserian ganglions, and advanced along the great superficial petrosal and maxillary nerves, respectively. There were differences in different animals.

In thinking of afferent qualities in the sympathetic nervous system, the sensory origin of some of its cells comes to mind.

None of this argument is other than speculation, based on some anatomic data in connection with the sympathetic nervous system. The most generous thought of it is that it may possibly be considered as a theory of the nasal asthma mechanism.

The clinical side of the question, however, is a set of simple facts. All of us have from time to time read of, and possibly observed, strange phenomena in connection with the nose. We read also of the general application of cocaine and of many procedures in the nose, curing or helping asthma. My personal experience along these lines has always been disappointing. Removal of polyps, for instance, at my hands, has never influenced asthma; but I know well that others have been more fortunate. This is true also of resection of the septum, and the treatment of the anterior paranasal cells.

I have, however, been much more fortunate in the treatment of the posterior part of the nasal cavity. Here, to my mind, the question is one of whether or not the condition is due to irritation of the sympathetic nervous system, either in the nasal ganglion or in the course of the vidian nerve as it passes forward through the floor of the sphenoidal sinus.

If this be correct, I can understand how in some cases the sympathetic fibers, as they course from the nasal ganglion into the nose in some specially irritated states, might be the starting point for the reflex, instead of a point further back, to wit, the ganglion or the vidian. Practically, however, this has not been my experience.

If the asthma reflex may be best controlled from the nasal ganglion or the sphenoid sinus, they should also be the places from which the reflex may at least sometimes be started experimentally, or accidentally. This has also been my experience, as the following will indicate:

REPORT OF CASES

CASE 1.—The application of horse serum to any part of the patient's nose in an instance of horse asthma, was very irritating, producing at once sneezing, swelling and serous secretion; but the asthmatic attack was produced only from the nasal ganglion region. A subcutaneous injection of sufficient horse serum brought on asthma.

CASE 2.—In a case of severe asthma, with upper and middle meatus polyps, the middle turbinate and middle meatus polyps had been removed with the anterior ethmoid cells on both sides. The procedure had, of course, required a considerable cocaineization; but neither the surgery nor the cocaineization had at all influenced the asthma. Whether the upper meatus lesion was recognizable by the rhinologist at that time, is unknown to me. The case was clearly recognizable when the patient consulted me, one year later. I at once performed the nasal ganglion experiment of cocaineization, trying to help it. A drop of 40 per cent. solution was applied to the sphenopalatine foramen, and at once relieved the asthma. The patient stated that that spot had never been touched before. He did not know I had used cocaine, or where I put it. I opened the postethmoidal and sphenoidal cells later. The sphenoid was full of polyps. The bone lesion is not controlled. Polyps reform, and he still has asthma. An autogenous vaccine of staphylococci has helped the bone lesion, and the asthma is much better. A coryza reestablishes all of his troubles, polyps and asthma. This case is of twenty years' standing. Epinephrin administered subcutaneously stops the asthma.

CASE 3.—In an instance of long standing and great severity, in every way similar to the one preceding, cocaine applied to the nasal ganglion was found to have a reversed action. Instead of helping, it at once made the attack violent. This is a rare reaction, seen sometimes in the treatment of nasal ganglion neuralgia.¹ The patient, in this instance, has been greatly helped by the postethmoidal sphenoidal operation.

CASE 4.—In another case of five years' duration, with lower-half headache, the reflex and pain were controlled from the nasal ganglion. I injected it twice with 95 per cent. alcohol containing 5 per cent. phenol (carbolic acid). The pain is stopped; a very slight degree of asthma returns from coryzas. In this case the headache and asthma are brought on at will by application of irritants to the sphenopalatine foramen, as, for example, by a 2 to 50 per cent. silver nitrate solution. Other areas in the nose do not respond to this experiment.

CASE 5.—A 2 per cent. menthol solution in oil produced a severe attack of asthma in a case of severe sphenoidal headache (after the cells had been opened five years) in an effort to find an intrasphenoidal application which would be helpful and lasting in effect. The sphenoid had been filled with solutions of iodine, sodium salicylate, oil of wintergreen, and phenol. The menthol alone produced asthma. Coryzas, in this case, produced lower-half headache, often severe, but not asthma.

CASE 6.—In a case of autumnal hay-fever, with asthma, the intrasphenoidal application of ragweed pollen extract, in mid-winter (ground covered by 3 inches of snow) produced asthma. The intrasphenoidal application of cocaine during the attack of hay-fever stops the asthma.

In young patients, postethmoidal-sphenoidal lesions producing asthma are often accompanied by fever. I have thought, in trying to explain the fever, that they were probably accompanied by bronchitis; but I am not sure of this, because I never see the children in these attacks—they are always brought to me after the attack.

CASE 7.—In a child, aged 6, very intelligently nursed, tachycardia is always present and lasts for about two weeks after the asthmatic attack is over, suggesting that the tachycardia is, in this case, a reflex from the nose, and of the above-detailed mechanism. The attacks are always accompanied by fever.

⁹ Kuntz: Further Studies on the Development of the Cranial Sympathetic Ganglia, *J. Comp. Neurol.* 21.

CASE 8.—In another case, every coryza that affects the olfactory fissure produces asthma, for the time, of the coryza.

INFLAMMATORY CASES

In some of my cases, intelligent effort to prove some sensitization to proteins failed to reveal it. These cases were apparently of local inflammatory origin. Some were acute, and some were chronic hyperplasia, without bacteria that could be grown by our present laboratory methods. Others, such as the hay-fever group, are clearly sensitive.

Clinically, the local inflammatory cases depend for their relief on the control of the local lesion. Aside from the indicated surgery, an autogenous vaccine, when bacteria can be grown from the lesion, is sometimes helpful, making the interval between coryzas longer. The cure of the case depends on the cure of the local lesion. Inasmuch, however, as no preventive for coryzas is known at present, the acute inflammatory action so produced in that district is apt to rekindle the trouble. This has been my experience. The patients may be much relieved, just as headaches from such lesions may be very greatly relieved, but there are almost sure to be recurrences, just as a coryza in that district can always make headache, because the nerves remain in their vulnerable positions, and are affected by the inflammatory action.

Thought of the sympathetic nervous system in relation to asthma, as here detailed, raises the question of why there are not more cases of this kind; or of why not all patients suffering from nasal ganglion or vidian nerve lesions have asthma; or of why some have asthma only, and no other manifestation, from a most pronounced lesion of these parts. There does not seem to me to be any direct answer.

Speculation, however, continues with the thought that there may be anatomic variations sometimes which explain some cases; for example, the (normal) fibers of the cervical sympathetic nervous system arise in the thoracic nerves and pass up to the superior cervical ganglion (preganglionic neurons), and from this ganglion proceed (postganglionic neurons) to or through the nasal ganglion. Should, however, these arrangements be changed and the relay station be the lower cervical or first thoracic ganglion, there are met the vasomotor fibers for the lung and accelerator fibers for the heart. In what way the reflex is then transferred is beyond speculation.

SENSITIZATION

In this immediate association of thoughts comes also the question of sensitization. Some nasal ganglions and vidian trunks are sensitive to things that do not affect others, as, for example, Case 4, in which the patient was sensitive to silver nitrate solution locally, and in Case 5, in which the patient had a vidian trunk sensitive to menthol. In both of these cases asthma is produced by these irritants. Probably for all hay-fever patients, the ganglion is sensitive to locally applied pollen extract; but if the anatomic arrangement of the sympathetic nervous system is normal, they have hay-fever without asthma. Should, however, the lower cervical or first thoracic ganglion be the relay station, that patient may develop the asthma. (The questions of sensitization in general cannot be considered here.) That there are anatomic variations in the sympathetic nervous system seems certain to me from my observations of the nasal ganglion. Sometimes the pupil

dilates from cocaineization of it, and once I saw the eyelid droop from it; and I have seen the cocaineization of the ganglion of one side stop pain on the opposite side.¹⁰

NASAL OR SPHENOPALATINE NEUROSIS*

HARRY L. POLLOCK, M.D.

CHICAGO

In 1914 I presented a paper on the "Injection of the Sphenopalatine Ganglion in some of the Commoner Diseases of the Nose." I was very much surprised to learn that the average rhinologist did not interest himself in this particular phase of our specialty. In the past few years, however, considerable interest has been taken in the subject, although there is not, even now, attributed to it the importance which I consider it deserves.

To understand the etiology of these various neuroses, a fairly clear conception is necessary of the anatomic relationship of the ganglion to the various accessory sinuses of the nose; therefore I will review the anatomy of this region rather extensively. The sphenopalatine, Meckel's or nasal ganglion is deeply placed in the sphenomaxillary fossa, close to the sphenopalatine foramen. It is triangular and is situated immediately below the superior maxillary nerve, just as it passes the fossa. Its sensory root is derived from the superior maxillary nerve, through its two sphenopalatine branches. Its motor root is derived from the facial, through the large superficial petrosal nerve and the large, deep petrosal nerve. These last two join before their entrance into the ganglion to form the vidian nerve; its sympathetic root from the carotid plexus.

The branches of distribution are in four groups: ascending, which passes to the orbit; descending, to the palate; internal, to the nose, and posterior, to the nasal pharynx (Gray). The ascending branches supply the mucous membrane of the postethmoidal and sphenoidal sinuses. The descending branches are distributed to the roof of the mouth, soft palate, tonsil and lining membrane of the nose. The internal branch is distributed to the septum and outer wall of the nasal fossa, and to the mucous membrane behind the incisor teeth. The posterior branch is distributed to the upper part of the pharynx and to the region behind the eustachian tube.

As can readily be seen from the wide distribution, there are numerous points which may be irritated and cause symptoms, either locally or reflexly at some distant point. Nevertheless, owing to the great area of the nasal mucosa, including the lining of the nasal accessory sinuses, to the fact that the mucous membrane is brought into contact with various irritating substances by breathing and to the further fact that the sinuses are often the seat of suppurative processes, we must look here for most of the causes that produce symptoms of nasal ganglion neurosis.

Most textbooks state that the ganglion lies in the upper portion of the sphenomaxillary fossa, but does

10. An extensive interesting historical résumé of the observations on asthma is to be found in Brown, O. H.: *Asthma*, St. Louis, C. V. Mosby Company, 1917.

* Read before the Section on Laryngology, Otology and Rhinology at the Seventeenth Annual Session of the American Medical Association, Atlantic City, N. J., June, 1919.

1. Pollock, H. L.: Injection of the Sphenopalatine Ganglion in Some of the Commoner Diseases of the Nose, *Illnesses M. J.* 27 (May) 1915.

not explain its relation to the various accessory sinuses which surround or are in intimate contact with it. To understand some of the etiologic factors causing neuroses of this ganglion, it is necessary to study the relation of the ganglion to the accessory nasal cells. I quote from Sluder:

Relation of the Nasal Ganglion to the Wall of the Paranasal Cells.—When the upper boundary of the fossa is made entirely of the sphenoid sinus, the ganglion lies in close relation to the sphenoidal sinus; when the upper boundary of the fossa is made by the sphenoid sinus in its posterior half, and by the posterior ethmoidal the anterior half, the ganglion lies in close relation to both. When the sphenoid sinus is prolonged downward and forward, the ganglion will lie in close relation to it, in front. When the sphenoid is prolonged downward into the pterygoid process, the ganglion will then lie posteriorly in close relation to the sphenoidal sinus. Anteriorly, the fossa is formed by the wall of the maxillary sinus, but the ganglion can never lie in close relationship to this wall because of the pad formed by the arteria-palatine descendens and the arteria-pheno-palatina with their accompanying veins and the surrounding connective tissue.

Relation of the Nasal Ganglion to the Lateral Wall of the Nose.—The sphenopalatine foramen is accurately placed at a point just posterior to, and immediately above, the posterior tip of the middle turbinate. The ganglion usually lies close to the plane of this foramen. The ganglion does not, however, always show the same relation to the foramen. I have found it as close as one-half millimeter from the general membrane of the nose, and as far as nine millimeters.

Judging from this close relationship of the ganglion to the accessory sinuses, one cannot but believe that an inflammation or suppuration in these sinuses must at times involve the ganglion itself, and give rise to the neurosis which we so often find.

Clinically, we divide the neuroses into two great classes; namely, the neuralgic and the sympathetic (Sluder)³. When a patient presents a clinical picture of a ganglion neurosis, one must attempt to ascertain the underlying pathology and correct it before attacking the ganglion itself.

The neuralgic syndrome consists of pain, intense and excruciating in character (in some, cases of milder variety), radiating to any and all points supplied by the branches of the ganglion. The typical location of the pain is over the root of the nose, in and about the eyes, over the frontal region, into the pharynx and tonsil region, in and around the ear, posterior to the mastoid, into the occiput, to the neck, the shoulder, the arm and, at times, even to the fingers. The most severe and constant pain seems to concentrate at a point about 6 mm. back of the mastoid. Not all patients present this typical picture, as usually only one or more of the named are involved; but I have seen a few cases in which all of them were affected at the same time. In practically all of these types of cases, the pain just posterior to the tip of the mastoid is present.

When a patient presents this clinical picture, the diagnosis is simple. All local points of irritation or inflammation must be searched for and corrected before an attempt is made to attack the ganglion itself. By these points I mean the teeth, gums, deflected septum or spurs, and all sinus diseases, either suppurative or non-suppurative.

I have described the sympathetic syndrome before;⁴ The condition comes on at any time of the year, is

irregular in its time of appearance, duration and severity, and is in no way associated with the ripening of the various pollens, to the inhalation of which hay-fever has been ascribed. On the contrary, those of my patients who have had these symptoms for a number of years inform me that the attacks scarcely ever occur during August or September, and that if they do, the severity of the attack is lessened.

The paroxysms are often brought about by contact with or inhalation of a specific kind of perfume, a particular flower, the odor of various animals, a slight draft of air, or the inhalation of ordinary dust; or they may come on apparently spontaneously. These paroxysms usually begin just on arising, with attacks of sneezing. The patient sneezes from five to fifty times, and the attack is followed immediately by a profuse watery discharge from the nose. At the same time there is a reddening of the mucous membrane of the eyes, accompanied by profuse lacrimation. The nose becomes blocked, and breathing is naturally difficult. These symptoms may be of short duration, lasting only an hour or so, or they may continue for six or eight hours, and then suddenly abate, only to reappear on succeeding days, or when the patient is again brought into contact with the specific irritant. Some of these acute attacks may continue for a week or ten days, and some, only a day. The appearance of the nose between attacks, is usually normal except, possibly, for a slight paleness of the mucous membrane. During the attacks, however, the turbinates are swollen, soft, pale and edematous, and have a boggy appearance. This is especially true of the inferior and, to a lesser degree, of the middle turbinate. The mucous membrane of the septum is also pale. The eyes are red, the conjunctiva is injected, and at times there is an accompanying itching.

The secretion is thin, watery and acid. After a few days of the attack, the upper lip becomes irritated and excoriated from the constant clearing and blowing of the nose, and from the acid reaction of the secretions. Even the entire tip of the nose may become red and swollen from the same cause.

Just why some of these cases present symptoms of the neuralgic and some of the sympathetic type is difficult to explain. We know, however, that other ganglion present the same phenomena. The lenticular ganglion, for instance, when inflamed, may have its sensory cells or its motor cells affected. In the one case we have pain, or perhaps herpes oticus, and in the other we may have a facial paralysis as first described by J. Ramsay Hunt.⁵

The prognosis of these neurosis is always bad if left alone. When proper treatment has been resorted to, the prognosis is naturally improved; but at this point I desire to state emphatically that the brilliant results which we desire or ought to expect in the neuralgic type are not often achieved. When perchance we do succeed in stopping these severe pains, if only in a small percentage of cases, the results certainly justify the efforts in this direction.

That we secure temporary relief, say, for a few months, can readily be explained by the work done by Otto May⁶ on the alcoholic injection into various nerves of animals. He has shown that alcoholic injections do not destroy completely the nerve fibers and

nerve cells, as they recover their function a few months after the injection. The alcoholic injection does, however, inhibit the function of the nerves for that length of time and, as a consequence, we obtain during this period, a cessation of the symptoms produced by an inflamed nerve or ganglion. We do not often penetrate the ganglion itself, but only bathe the surface with the alcohol which we inject into the sphenomaxillary fossa. We obtain a much larger percentage of cases of improvement in the sympathetic neurosis than in the neuralgic type. In a large percentage of these sympathetic affections we obtain complete cure and, in practically every case, an improvement in the symptoms.

TREATMENT

As I stated before, all pathologic conditions of the upper respiratory tract must be corrected; and these conditions include those affecting tonsils, teeth, gums accessory sinus, deflection and spurs on septum.

We have had one case referred to us in which a mastoidectomy had been performed to relieve the severe pain located just back of the mastoid proper. No relief was obtained; the diagnosis had been made of a primary mastoiditis, but at the operation no pathologic condition was found. In taking a roentgenogram of the teeth, we discovered an upper impacted third molar, the removal of which cleared up the condition completely.

I now have a young woman under treatment who developed a typical neuralgic syndrome, following an attack of influenza. Hers was one of the most aggravated cases I have ever seen. She had her ethmoids completely extirpated, and the sphenoids opened, without relief. An otologist diagnosed primary mastoiditis and performed a simple mastoid operation, but found no pathologic condition. I injected the ganglion with a 2 per cent. phenol alcohol solution, and it lessened her pain decidedly, although it did not destroy it completely, so that now no narcotics are necessary, whereas, formerly, large doses were required to give her some relief.

One of the most valuable prognostic points is the application of from 20 to 90 per cent. cocaine solution in the region of the sphenopalatine foramen. If this stops or ameliorates the pain to a great degree we can be reasonably positive that the injection of the ganglion will give good results.

The technic is simple. I first cocaineize the posterior end of the middle turbinate and the wall just behind it, with a 20 per cent. solution of cocaine. Then a sword needle of Sluder is employed, a straight needle $5\frac{1}{4}$ inches long with a cross bar near the end. The needle is introduced from the septal side of the nose. I transfix the posterior end of the middle turbinate and press the needle gently through the turbinate until the posterior wall is felt. The needle is then pushed upward, outward and backward through the bony wall which is the anterior boundary of the sphenomaxillary fossa, in which the ganglion lies surrounded by connective tissue. Usually, by tactile sense, one feels the needle slip into the cavity. The ganglion is about 0.66 cm. back of the wall. A 5 c.c. Luer syringe, filled with a 2 per cent. solution of phenol (carbolic acid) in alcohol is then attached to the needle, and from 5 to 15 minims are injected. If the needle succeeds in penetrating the ganglion, the patient complains of excruciating pain in the eye, ear, top and back of the head and in the shoulder, but should the phenol alco-

hol solution merely surround the ganglion, the pain will be less severe.

The pain usually lasts anywhere from a few minutes to twenty-four or forty-eight hours, and it is in cases in which the pain is prolonged after injection that the end-results to the patient are most gratifying. The number of injections necessary is variable. If the ganglion is penetrated the first time, as indicated by the severe pain, only one injection is required. If not, two, three or four attempts may be made at intervals varying from a few days to several weeks. If no relief is obtained after four such injections, I feel that further attempts would be useless. Often we find the posterior wall so thick that it is impossible to push the needle through, and in these cases I have resorted to the use of a mallet to drive it into the cavity. In using the mallet one is not so sure of being in the proper place, so I usually withdraw the needle and then reintroduce it by tactile sense, as I then have a far better knowledge of where the end of my needle is.

I have not said anything concerning the medical treatment of or rather topical applications to, the region of the sphenopalatine foramen, for the reason that in my experience I have seen nothing but the most transitory results occur from these applications, and do not believe the method worth trying.

SUMMARY

In every case in which a diagnosis of nasal ganglion neurosis has been definitely established, we should at least attempt to give patients permanent relief from the severe neuralgias. That we do not obtain as large a percentage of results as we desire may probably be due to faulty technic. Nevertheless, on account of the simplicity of the injection and the freedom from danger, it ought, in every case, to be given a trial, as nothing is to be lost and everything gained. Even if only transitory results, say from four to nine months' duration, are obtained, we have accomplished much, as the patients can be injected at the expiration of this period with probably less danger than before.

108 North State Street.

ABSTRACT OF DISCUSSION

ON PAPERS OF DRS. PREAKER, THOMPSON, SLUDER
AND POLLOCK

SIR ST. CLAIR THOMPSON, London, England: This is a most interesting subject and I have heard much of it for twenty-five years. I am afraid we have all talked of it and heard of it, and "evermore came out by the same door by which we entered." I am inclined to think that just as the lunatic, the lover and the poet are of "one nature, all akin," so hay-fever, rhinorrhea, spasmodic sneezing and asthma are somewhat of "one nature, all akin." What that nature is, I am not prepared to say, but I think there are more things in our inheritance and in our nervous system than are dreamed of in our rhinology.

Inquiring into the history of many of these patients we find that they come most distinctly from what, for want of a better word, we call the neurotics. I will not go as far as the man who said his practice was confined to the neurotic, the erotic and the tommyrotic. He was a neurologist. But in tracing the history of these people I have been struck by finding that a patient who has hay-fever or attacks of sneezing, had a father who had asthma, and I have lived long enough to find that that patient who in youth or adult life suffered from sneezing and rhinorrhea will get quit of it and in later years become a wheezy, placid old gentleman with bronchial asthma which takes him off to the silent realm. So that part of the subject I would suggest that we do not forget.

I endorse everything Dr. Thompson said in his paper, which my own experience entirely confirms. A few years ago the term "vasomotor rhinitis" was used, but the word "hydrorrhea" is better. I think I understood the doctor to say that cerebrospinal rhinorrhea came from traumatism. I have seen two cases where there was no traumatism, and by searching the literature and analyzing the cases reported by Bosworth in the earlier edition of his textbook, I find that he found, from postmortem records, that several of his cases were cases of cerebrospinal rhinorrhea. Of the two cases I had I have published one, and in that my conclusion was that the poor girl, 22 years of age and unmarried, with no bad family history, died of cerebrospinal rhinorrhea, at the time thought to be meningitis. My other case was seen in consultation with Sir Victor Horsley, and he threw out the suggestion that he was not sure it was not syphilitic. I have not published that case yet, although I have the notes and intend to do so; but the postmortem findings showed that Sir Victor Horsley was right, it was a syphilitic neurosis of the anterior fossa of the skull; but it was a case of rhinorrhea.

In regard to the tests, nasal rhinorrhea secretion contains mucin, while the cerebrospinal rhinorrhea secretions contain glucose or some other variety of sugar reducible by Fehling's solution. But there is a simple test, and that is, that with nasal rhinorrhea the handkerchief of the patient, when soaked, becomes stiff, as if it were starched; while with the cerebrospinal rhinorrhea the handkerchief remains soft. I have seen many cases that were not recognized because they did not give a Fehling's reaction; but if the fluid is not tested within an hour the sugar decomposes and you get no reaction. The other points Dr. Thompson brought out are all admirable, the fact that climate and age make very little difference, that the patient dies a natural death; also that the effect of the cerebrospinal rhinorrhea is more or less continuous, while the real rhinorrhea has its periods of intermission.

As regards treatment, I will never forget a paper read some twenty years ago by Dr. William White, the great surgeon of Philadelphia, on the success of the operation per se. He gave a record of cases out of his enormous experience, in which he had operated for symptoms, say abdominal or hemiplegic, and after he had done all this work, the patient got well. I think we should probably remember this in all the treatments we suggest. I do not wish to depreciate research in this condition; I think it is most admirable, and any of us who have had relatives or friends suffering from the agony of trigeminal neuralgia, will welcome the injection of alcohol or anything that will give them relief. We have a saying that the German doctor kills you, and the English doctor lets you die. I think, therefore, that both of us ought to cross the Atlantic and learn from you and your society how to make the patient comfortable.

Dr. WOLF FRIEDENTHAL, New York: From a clinical point of view it seems to me that the action of sneezing is analogous to that of coughing. That is, just as an effort is made from the lungs and lower respiratory tract to bring up the secretions or foreign bodies that get down into the deeper bronchi by coughing after the epithelia have brought them to the upper air tract, so it is natural that when any foreign body or substance gets into the nose, we should want to get rid of it in some way. In the lower area we can blow it out but when this foreign substance gets into the region of the nervus (rhinoidalis) we cannot do so; in many instances it requires further action, and that act is sneezing. I do not understand the doctor's explanation of the action of the soft palate. After one or two inspirations we make an expiration. It seems to me the most natural thing that the palate would do is to close up. Is it open during this action, or can we keep it closed and yet sneeze? From the doctor's description we see that from many points in the system impulses may be brought to the nose. From a clinical point of view, I want to remind you of the epistaxis that occurs during menstruation and the attacks of sneezing that occur before the end of menstruation. On the other hand, impulses that start in the nose may go to any other part of the body, including the lungs and bronchi. In reference to Dr. Thompson's paper

I have seen about six such cases. There is no doubt that an angioneurosis is at the bottom of the disturbance. I have seen one case of rhinorrhea cerebrospinalis of the type described by St. Clair Thomson. No treatment seemed to make any impression on the patient. After six years she had an acute frontal sinusitis. I operated and she recovered soon afterward. Three or four years ago this rhinorrhea suddenly appeared again. A very peculiar fact was that after she left the hospital I was called to her house on account of a swelling over the frontal sinus, the side operated on. I ordered the usual medication and next day the swelling was gone. About eight days later there was an edema over the other frontal sinus and over the antrum. I knew then that it was an angioneurosis.

In regard to the papers of Dr. Sluder and Dr. Pollock: In trying to solve the problem of the acute asthmatic attack by physiologic experiments and in trying to look into the etiology of this condition during the attack—I studied this condition thoroughly—and am inclined to believe that the sympathetic nerve is the most important one during the acute attack. I would, however, like to remind those who do this work that the sympathetic and the vagus nerves are so interwoven that often we do not know which is the action of the sympathetic and which is that of the vagus.

Dr. EMIL MAYER, New York: I have been greatly interested in this splendid presentation of Dr. Brubaker as I feel that it throws light on a question that I have not as yet been able to answer satisfactorily. It may help also to explain the effect of affections of the sinus on asthma in showing a direct connection between the nose and the spinal column. I have at various times called attention to the remarkable results following the use of cocaine and trichloroacetic acid applied to certain sensitive spots in the nose in cases of dysmenorrhea. It is really remarkable to note the prompt relief sometimes occasioned when women are in very great pain, unable to move about, pale and listless, and then to see their color return and absolute freedom from pain immediately follow this application to the nose. While the fact of relief in a large majority of cases has become fully established, the explanation as to why it occurs has until now not been sufficiently clear. It has been shown here that there is a direct connection between the nose and certain ganglions. Dr. Sluder asked one question: Why are there not more of these cases? The answer rests with the general practitioner. When he knows as much about these cases as we do, there will be more cases. I can say from my own experience in a large general hospital, in association with a visiting staff that made thorough examinations, there were daily requests from the physicians for examination and report on their patients by the laryngologist as well as by the other specialists whose opinion might be desired. In this way I had occasion to see many cases of asthma that would ordinarily not come to the laryngologist, and the number of cases were by no means as few as they would seem to be from the question put by Dr. Sluder.

I do not recall that Dr. Thompson spoke of the advantage of the internal administration of arsenic in the cure of these cases of hydrorrhea. I have used this remedy successfully in a number of cases of this affection looking on them as being analogous to affections of the skin. This is a field which many of us have overlooked. I have found a number of instances in which there was a remarkable similarity to the skin diseases in the mucous membrane. In a recent case of hydrorrhea I told the patient that I was going to give her some arsenic to relieve her trouble and she then informed me that some years previously she had had an affection of the skin which was entirely relieved by the internal administration of that drug and hence she was glad to take it in this present instance. The result was entirely satisfactory and the patient has remained well.

Dr. OSVELL H. BROWN, Phoenix, Ariz.: The hypersensibility of this ganglion may play an important part in asthma. Asthma is a very complicated condition. As a disease it must have one exciting cause, although it may have many contributing causes, and in my opinion the probable cause may overshadow the essential, primary and direct cause. The muscular effort in normal inspiration and expiration is

wholly a passive process. In forcible expiration the air gets tangled up and in an effort to get out it rushes from one cell to another. That produces a much increased intra-alveolar pressure. It presses on the blood vessels, not only the chest but the abdomen. Theoretically, then, asthma might be produced in a normal individual by prolonged forcible expiration. Given, then, this condition which ordinarily produces this nonpassive expiration, without bronchitis, without nasal infection, without hay-fever, and there is an ideal condition for the individual to become asthmatic. Often there is also a pulmonary phthisis, and that helps to keep up the inflammatory condition. I have often wondered whether hay-fever was not due to focal pathology of the nose; but whether it is or is not we must get at the focal condition, and we must not forget that any inflammatory conditions around the nose or respiratory tract contribute to the pathology, and that an inflamed appendix or prostate can help to keep up this process which originally started in an inflamed sinus. Whatever keeps up the hay-fever condition must be ferreted out, and desensitization or removal of the pathology should be recommended.

DR. JOSEPH C. BECK, Chicago: One point impressed me with reference to the etiology, and that is the "etiology of the etiology." The gentlemen do not go far enough. Dr. Thompson merely touched on the subject by saying that the question of the endocrinology or what the internal secretions have to do with hydrorrhea nasalis is not in place. I do not know whether he meant that we were not fit or able to discuss the subject. However, I believe that the question of asthma and all this matter of sensitization is a disturbance of the glands of internal secretion. For instance, I do believe that the suprarenal glands play a most important part in the chemical change in the blood as, for instance, in the calcium content. You know how Wright of England treated the question of angioneurotic edema by administration of large doses of calcium. Crile has shown that marked changes take place when the suprarenals and other glands of internal secretion are affected and how the calcium content is changed. Give a large dose of epinephrin hypodermically to a patient during an attack of asthma and, as a rule, it has an effect. I believe that this is due to the hypoepinephrinization, and that day by day the dose will have less effect because there is a tolerance developed and the etiology of the etiology has not been studied and removed, that is, to know what is the cause of the disturbed condition of the suprarenal glands. It is well known that chronic infection, whether from bowels, appendix or teeth, produces a change in these glands, and there I think lies a great part of the trouble, the etiology of the etiology.

In reference to the affection of the ganglions and the work of Sluder, as presented by Dr. Pollock in his paper, there is not enough emphasis laid on the fact that men will not try this method of treatment because some other man says "I have tried it and it is no good." I had a patient referred to me recently by a neurologist in Chicago who has recognized that this ganglionic disturbance exists and has come to stay. It was referred for ganglion injection. The patient was difficult to anesthetize locally, so had to be put under general anesthesia. The operation was followed immediately by paralysis of the pupillary sphincter and the motor muscle (internal rectus). There was a loss of sensation to the cornea. We ought to be careful in such sphenopalatine cases where this complication occurs not to lose an eye following the injections.

DR. JOHN A. THOMPSON, Cincinnati: The necessity of writing a paper that can be read in fifteen minutes precludes any mention of the bibliography. Perhaps for the reason of condensing I spoke of the escape of the cerebro-spinal fluid as being traumatic. I meant to include in that form those cases where the escape is caused by disease. A woman had an aphonia for nine months. She had a laryngitis secondary to a badly deflected septum. I straightened the septum and found behind that a bad infection of the posterior ethmoid and sphenoid. When I opened these cavities the dura was bare for one by one and a half inches; you could see the brain pulsating. A careful examination showed there was no bone between the nose and brain, and a very little fur-

ther extension of the diseased condition might have caused a fatal meningitis, or by perforation of the dura permitted the cerebrospinal fluid to escape. Most cases are traumatic in the sense we usually use the word, but in other cases the perforation is through disease.

In regard to Dr. Beck's statement that we have not gone far enough with the etiology of the etiology, I meant only to say that so far there has been no observation, either experimentally or clinically, to show the relationship of the endocrine glands to nasal hydrorrhea or rhinorrhea, whichever term you prefer. As for asthma: While cases of nasal asthma do occur, in a majority of these cases the cause is outside the nose. Treating these patients by tracheal injection for twenty-eight years I have come to feel that bronchitis exists in all cases of asthma. If you will cure the point of infection from which the acute attacks spread out, you will cure many more cases of asthma than you do by treatment through the nose.

DR. GREENFIELD SLUDER, St. Louis: Dr. Beck spoke of some unfortunate experiences with the injection of the nasal ganglions. I, too, have had some unfortunate experiences. In the course of probably 1,500 injections I have had hemorrhage four times, once a hemorrhage of clinical issue immediately on the insertion of the needle. Three times I have had secondary hemorrhage. If an accident happens, it seems to me it punctures the internal maxillary artery rather than the sphenopalatine. When a hemorrhage occurs it must be packed at once, but that packing is very easily inserted and the flow is easily controlled if you follow the track of the needle. If one does not know the origin of the trauma and attempts to pack such a case, he must pack anteriorly and posteriorly. I have also had the misfortune to paralyze the external rectus. When that happens it can be explained by the connective tissue of the sphenomaxillary fissure being unusually loose, permitting the flow of the alcohol upward and outward. I believe Dr. Beck's trouble would have been avoided by the very slow instillation of the alcohol.

DR. HARRY L. POLLOCK, Chicago: Regarding the nasal hydrorrhea of the sympathetic type: In order to make a diagnosis of the sympathetic type, I stated that all pathologic conditions must be excluded. In some cases Dr. Thompson said polypi were present. In my cases where I diagnosed sphenopalatine neurosis of the sympathetic type, everything was normal, except a slight paleness of the mucous membrane, so I think we had a noninflammatory ethmoiditis. In regard to the treatment of this sympathetic type: It is explained by my chart. I have had many of these cases, and if you shut off the afferent impulse you are bound to cure the patient at once. In regard to the cause of asthma: I presented a paper on this and went very thoroughly into it, to find what was the underlying cause of asthma. Polypi, focal infections, split proteins, these are not the real cause, but the underlying principle of all is the altered secretion of the ductless glands. You may have one patient with nasal polypi and asthma, and the next twenty-five will have a nose full of polypi and no asthma. More cases of nasal polypi are complicated by asthma than not. I believe it is due to the altered secretions of the ductless glands; otherwise every patient with polypi would have asthma.

An Early Spanish Physician.—Dr. Francisco Javier Balmis, a Spanish physician, was, while residing in Mexico, the individual selected by the Archbishop-Viceroy of that country, to take to Europe specimens of the plants of the agave and begonia, which were in favor at that time for the treatment of venereal diseases and scrofula. In 1804 he was ordered by the king of Spain to introduce vaccination against smallpox in the Spanish colonies and at the same time to establish boards to promote its use. He did this in the Canary Islands, Porto Rico, Cuba, and in Venezuela, Guatemala, and New Spain (Mexico), and also introduced it in the English settlements and among the Moors and Chinese in Asia. He wrote a number of articles on these subjects.—From Beristain's *Bibliografía Mexicana*.

TRAUMATIC NEUROSES IN WAR AND IN PEACE*

T. H. WEISENBURG, M.D.

PHILADELPHIA

For a period of four months I was on duty in U. S. Army General Hospital No. 30, Plattsburg Barracks, N. Y. This hospital was the only so-called war neuroses hospital conducted by the War Department in this country. There were three groups of patients: (1) those who had been sent from camps in this country; (2) soldiers who had been in France but who had not seen any actual fighting, and (3) soldiers who had been in combat. The majority of these cases, no matter what their source, were sent to Plattsburg because they were difficult to cure.

This was particularly true of the over-seas cases. It is, of course, known that a majority of the patients were cured in front line stations, and that those who were not thus cured were sent to Base Hospital No. 117 or to other centers. The more refractory of these cases or those that seemed to be incurable, or that for some reason or other did not offer favorable conditions for cure, were returned to the United States and to Plattsburg.

HYSTERIA

Of the patients studied in Plattsburg, those with hysteria attracted most attention. There were present the usual types which have been so well and often described, such as aphonia, stuttering, amnesias, paralyzes of both legs and more rarely of one upper or lower limb, less frequently a combination of mutism with deafness, a few cases of blindness, tremors, gait of various sorts, and a large number of so-called epileptic or fainting cases. There is no need of describing the symptoms in these cases, for the patients presented the usual pictures which are present in all. However, some unusual phenomena were observed. There was one case, which is worth particular mention, of a man who had a constant dancing of the eyeballs:

A boy, aged 18 years, with a normal history, after a particularly trying attack which lasted many days, and in which many of his companions were killed, began to develop a tremor all over his body with quick jerking movements of the head and a constant dancing of the eyeballs to which his lieutenant called his attention. This was in April, 1918. His tremors gradually lessened, but the movements of the eyeballs continued. It is interesting to note that besides having been gassed he had a flesh wound in the left leg, and a rifle bullet wound in one shoulder. Examination did not detect anything unusual, with the exception of quick reflexes; but there was present a constant horizontal nystagmus, which greatly increased under excitement, and almost disappeared when the patient was at rest or when free from exciting stimuli, and was absent when he was asleep. The ocular movements were quick and of wide range and were different from the nystagmus seen in multiple sclerosis or any other disease.

There is no reason why there should not be a hysterical tremor in the eyeballs, just as well as in any other part of the body, but that such a thing is possible, is interesting.

EPILEPSY AND HYSTERIA

One of the most difficult problems was the differential diagnosis of epilepsy from hysteria. It was com-

monly known by the soldier that fits would disqualify him for service and as a consequence, a great many so-called epilepsies developed. Of those patients returned to Plattsburg from the American Expeditionary Forces whose cases were diagnosed as epilepsy, a surprising number proved to be such, although there were a great many cases of hysteria diagnosed as epilepsy. On the whole, it cannot be said that war experience produced epileptic attacks; but undoubtedly in a number of patients, epilepsy appeared earlier than would have been the case in ordinary civil life. The diagnosis of epilepsy was nearly always possible after an attack was observed, although in a number of cases it was difficult.

There was no essential difference in the hysterias which developed in the patients who had had their entire service in this country, and in those who had been with the American Expeditionary Forces, including those who had been in actual combat, with the exception that in the home troops tremors were not prominent. There were several cases of so-called "trench back" or campicormia, all of them from this country. There were three instances of so-called reflex contractures in the hands and fingers. As is, of course, well known, Babinski and Froment believe that these are organic in character; the opposing view being held by others, notably Roussy and Hurst. In the few cases observed by us, we were able to effect a cure, and I have no doubt that they were purely hysterical in character.

It has been said that this war produced two new types of neuroses: (1) the so-called reflex contractures of the hand- and fingers, and (2) trench back or campicormia. I have seen some examples of the latter condition in civil life, and in January, 1918, I exhibited in a clinic, to a class of medical officers under instruction at that time in Philadelphia, a medicolegal case with a history of an injury to the hand, a typical example of reflex contracture of the hands and fingers.

SIMILARITY OF NEUROSES IN WAR AND IN PEACE

In view of this experience, the question naturally arises: Is there any difference between the hysterias of war and of peace? In my experience of a good many years with traumatic neuroses I have seen a duplication of practically every type of hysteria seen in Plattsburg, but, of course, not in such abundance and of such variety. In civil life, aphonia, stuttering, deafness and blindness are not so frequent; but paralysis, contractures, tremors and fits are common.

This view is not held by Schwab, who states that "the war neuroses are specific war conditions, and with the ending of the war they disappear from clinical experience. Their place is taken by the civilian neuroses, which are different things." The opposing view is taken by Leri, who believes that the hysterias of war and of peace are identical.

This difference in the point of view held by Schwab and by myself is, no doubt, due to the different conditions under which neuroses were studied. Many of the patients returned from France were so much better when they reached Plattsburg that they presented an entirely different clinical picture. Besides, their presence in this country virtually assured them that they would not be returned to France. Therefore the conditions surrounding them approximated a peacelike basis and offered an excellent opportunity for comparison.

*Read before the Section on Nervous and Mental Diseases of the 52nd Annual Meeting of the American Medical Association, Atlantic City, Pa., June 13, 1919.

Of the neuroses, other than hysteria, Schwab mentions neurasthenia; psychasthenia; hypochondriasis; anxiety neurosis; effort syndrome; exhaustion; timorousness or state of anxiety; concussion, (*a*) syndrome, (*b*) neurosis; gas, (*a*) syndrome, (*b*) neurosis.

As in hysteria, the clinical picture of these conditions changed materially, and only the neurasthenias and anxiety neuroses were at all prominent, although there were some psychasthenic and hypochondriac states. These neuroses were similar to those found in civil life.

INFLUENCE OF THE ARMISTICE

Some interesting observations were made regarding the suggestibility of patients and the influence of the armistice. It did not cause a very great change, and there were practically no spontaneous cures, although our work became much easier and there was a greater incentive for the patients to get well and less difficulty in getting them well. One interesting observation was made: Before the armistice it was possible to suggest new areas of disturbance of sensation or an increase of paralysis. This was impossible after the armistice, and the only suggestion that the patients took kindly to was that of getting well.

The suggestibility of hysteria was very well shown in the occurrence of "fits." Patients in whom attacks were absent for months suddenly developed them in times of stress; as, for example, when under arrest after an offense had been committed. One patient left the post under the impression that he had the right to do so, but on discovering that he was absent without leave, he developed a series of attacks lasting several days, giving this occurrence as an excuse for his absence.

PERSONALITY OF THE WAR NEUROTIC

There was, however, one very distinct impression made on all of the medical officers who were on duty at Plattsburg for any length of time. It was the first time that I have ever had the opportunity of living exclusively among neurotics, for any length of time. Because of the peculiar situation at Plattsburg, it being an old army post converted into a hospital with practically no outside attractions, the atmosphere of the place naturally was much more acutely felt than would have been the case if such a hospital had been located in or near a large city. I was sent to Plattsburg and was placed in charge of all treatment; that is, it was my duty to see that the patients got well. The patients were indifferent. They seemed to care about getting well and yet not to a very great extent. After the armistice, it was different. They wanted to go home, but the incentive for getting well was not even then what it should have been. The individual patients, while they were talkative, especially about their deeds of valor, at the same time were by no means so cheerful, openhearted and joyful as the average wounded soldier in other hospitals. Most of the patients were boastful, and wore all sorts of decorations, even wound stripes to which they were not entitled. On questioning, it was often found that some had put on wound stripes after they had been in a hospital with a mere cold.

Another noticeable thing was the difficulty we encountered in managing both enlisted men and officers. They were constantly complaining and finding fault. There were many who had been absent without leave. Every one who is familiar with the service knows that all soldiers grumble about everything under the sun.

This is a normal condition; but the patients in Plattsburg were certainly more difficult to handle than were those in other hospitals. Perhaps this should be expected among such unstable neurotics.

In other words, the conclusion was forced on me that the war neurotic, as seen in Plattsburg, was distinctly different from the normal individual; that he was boastful, somewhat depressed, erratic and certainly unreliable.

Numerous studies have been made of the personality of the war neurotic and of his neuropathic inheritance. Schwab states that the proportion of neuropathic cases in his experience was never under 2 per cent., or much greater than 5 per cent. When, however, it is taken into consideration that the more difficult and intractable cases were returned to the United States, it can be readily seen that the proportion of such individuals was much greater in Plattsburg.

TREATMENT OF THE WAR NEUROTIC

The treatment of the war neurotics in Plattsburg did not offer any unusual experience. The method adopted was similar to that found successful in neurologic centers abroad. The physicians, hospital corps men and nurses were instructed as to the nature of hysteria and war neuroses, and an effort was made to institute a so-called "atmosphere of cure," which was eminently successful. Electricity was only occasionally used. In fact, cases which were difficult to cure in France and in camps in this country offered no special difficulty, once the "atmosphere of cure" was established; for as happens in such instances, success led to success, and nurses and hospital corps men were as successful as the physicians.

As an example of this, I lectured one afternoon to those hospital corps men who were on duty at night. That same evening, twelve patients arrived from Camp Taylor, and were met by one of these men. Among these patients was a man who had paralysis of an arm, another who could not talk, a third who walked in a hopping manner, a fourth with paralysis of a leg, and a fifth with a very markedly bent back. On the way to the hospital, a hospital corps man told the patients of the wonderful cures that were made. I saw these patients on their arrival at the hospital and, seeing the good work that was being done by the hospital corps men, gave them instructions not to have them disturbed. The following day all these patients were well with the exception of the man with the bent back, who after one application of the faradic current promptly straightened up. This is an example of what can be done by an untrained attendant where there is good team work and the example of success.

TREATMENT OF THE PEACE NEUROTIC

The treatment of the traumatic neuroses presents different conditions. In the war neuroses, as has been generally accepted, the cause lies in a defense reaction to a personally intolerable situation, whereas in the peace traumatic neuroses, the causes can be assigned either to the desire of the injured for compensation, in the actual trauma produced, or in the fear of the consequences of the injury. I have had many years of experience with traumatic neuroses, testifying both for and against corporations, and I have always felt that the chief reason why so many of these cases last such a long time is that they are not disposed of immediately after their occurrence.

In the work of the Industrial Accident Commission of California, an excellent opportunity has been offered to study the final outcome of accident neuroses. Under the direction of Dr. Walter F. Schaller,¹ a special investigation was made of fifty cases. All but four of the persons were personally interviewed, and in all but two of them the factor for recompense was present. It is unnecessary to give in detail the results of this investigation, but it is interesting to note some salient facts:

Age was apparently unimportant.

Women showed a greater tendency to recover, although not one was entirely relieved.

The severity of the original injury apparently bore no relation to the outlook for recovery.

Most of the symptoms were predominantly hysterical.

The cheerful patients showed a marked contrast in recovering to those who were depressed.

Schaller emphasizes that of all the factors which enter into the course of the accident neuroses, the question of compensation is one of the most important, and its great psychic influence cannot be denied. This was not true, however, in all of his cases, for in three, there was recovery while the patients were still being paid under the periodic payment plan. The cases showing lump sum settlement proved the most favorable for recovery, early lump sum settlement being more favorable than periodic payments and a final lump sum settlement.

One very interesting phase of the investigation was the lapse of time between the injury and the recovery, the longest period being three years and nine months and the shortest, seven months. It can be seen from the foregoing that there is no basis of comparison, so far as cure is concerned, between the traumatic neuroses of war and of peace.

1106 Chestnut Street.

ABSTRACT OF DISCUSSION

DR. ROBERT MCGREGOR, Saginaw, Mich.: There does not seem to be any essential difference between war neuroses and the neuroses of common life. Whatever distinctions there are lie in the severe character of the causal conditions, the intensity of the symptoms and the facility with which the symptoms interchange between those of anxiety states and those of hysteria. I had the good fortune to see many of these cases in military hospitals in England and France and also in civilian hospitals in London among women and children as a result of air raids. I believe the problem of treatment is psychologic. At the same time one should not forget that many organic conditions are found to underlie these manifestations, and the victim of severe shock must always remain the potential epileptic.

DR. CHARLES A. ROSTWATER, Newark, N. J.: While on duty at General Hospital No. 30 at Plattsburg, I saw a case which presented features of unusual interest, and demonstrated, as stated by Dr. Weisenburg, that hysterical manifestations are induced by suggestion and can be cured by suggestion, even in cases of long standing. For about ten years a soldier had contractions of the right toes, with rigidity of the right ankle and partial rigidity of the right knee. He limped perceptibly, walked on the outside of the foot. He was unable to rest his weight on the foot. There was almost complete anesthesia of the entire leg. It appears that while working as a carpenter, his foot was crushed in an accident. Amputation of the toes was advised, but the patient declined and was treated by his physician for several months. For weeks the foot was kept in an elevated posi-

tion, followed by a period during which crutches and later a cane were used. When finally the dressings were discontinued, the doctor is said to have declared, "I saved your foot, but you will never be able to use it." In response to this suggestion, the patient never used his foot. It is difficult to understand how the soldier was considered fit for overseas duty, but, nevertheless, he was sent to France. While drilling he fell, and being unable to keep up with his company, was returned to this country with the diagnosis of "hysterical paralysis with contractions." Learning from him that he was a singer, I reminded him that if he held back the tones he could not sing, and explained to him that his inability to use the foot was entirely due to the fact that he was holding back the impulse necessary to move the muscles. I assured him that he was perfectly able to move the foot which was a trifle weak from disuse. He reacted favorably to the reeducation séances, and after a few days was completely cured, and walked as he did before the accident ten years ago.

DR. W. H. HICKS, Newark, N. J.: As a member of the advisory examining board of the state of New Jersey I saw many cases of psychoneurosis and I would like to ask Dr. Weisenburg if the psychoneurosis which occurred in many cases was due to a fundamental law of self-protection, a psychic inhibition, the best way for the patient to escape danger and founded on fear; if such was the case, how could one determine a real psychoneurosis that produced a monoplegia from a malingerer who had sufficient willpower to simulate monoplegia?

DR. LEWIS J. POLLOCK, Chicago: The policy adopted by the A. E. F. in the treatment of the psychoneuroses was such as to centralize the patients and to treat them as soon after the development of the condition as possible. For that reason relatively few cases were seen in base hospitals. However, during the early months of the active participation of the A. E. F. in this war it became necessary for a considerable number of these patients to be sent through base hospitals. I had the opportunity of observing about 350 cases of psychoneuroses developing at the front. Although agreeing with Schwab that the history of neuropathic hereditary taint did not frequently make its appearance, it was noted in a large percentage of cases that the patients themselves gave a history of having a certain type of make-up which we are accustomed to speak of as unstable. By this I mean that the individual had always been oversensitive, hyperimpressionable, easily upset, inclined to overscrupulousness or diffidence and embarrassment. Frequently he was the subject of various fears, as fear of lightning, high places, at times fear of loss of consciousness and rarely death or insanity. Though the fundamental features of the war neuroses are the same as those of civil life, the picture in its entirety differs in many respects in the cases observed in France from the condition met with in civil practice. This difference is probably due to the numerous conditions tending to produce the neurosis and which occur consecutively. From the time a man is inducted into the army until his return to civil life he is the potential possessor of a neurosis. Conditions in training camps, on transports, in rest camps, in cantonments, in France awaiting active service, in battle and in base hospitals on the way back from the line, all contribute to the formation of a neurosis. It is, therefore, rare to meet with only one type of a neurosis in a single individual. If a conversion hysteria develops in a soldier as the result of any condition which might be present, the rapid disappearance of the symptoms following the many defective methods of treatment does not mean that the man is well. Most frequently when the hysterical symptoms disappeared an anxiety neurosis was found to be present, the treatment of which was essentially a different thing and one marked by slow recovery and stubbornness. It is surprising to me to note that Dr. Weisenburg reports so many cases showing the stigmata of hysteria, as aphonia, paralysis, etc. Inasmuch as it was the policy of the neurologists in France to send to the United States only such cases as were constitutional and inasmuch as the hysterical stigmata, whether occurring in constitutional cases or not, were so easily cured, it occurs to me to inquire as to whether these stigmata did not redevelop during their journey homeward. I do not believe that the desire

¹ Schaller, W. F. Diagnosis in Traumatic Neurosis, J. A. M. A. 72: 108 (Aug. 11) 1918.

to avoid duty at the front contributed largely to either the formation of the neurosis or its incurability. It was not the fact that the individuals consciously wished to avoid service, but their character formation was such that they were unable to successfully cope with the situation and although frequently consciously wishing to "carry on," unconsciously the neurosis developed as a means of escape from a situation which produced a conflict between the man's social and moral desire and his incapability. It was only in this manner that the desire to avoid service contributed to the formation of the neuroses and not in the sense of disloyalty or cowardice.

DR. THEODORE H. WEISENBURG, Philadelphia: The differential diagnosis between hysteria and malingering is not easy, and in Plattsburg it was one of the most difficult of the questions that we had to decide. The reason for this is evident because hysteria itself is a motive disease, whereas in malingering the whole basis is that of a desire to deceive. I recall one case that gave us particular trouble. This man had a bent back. He developed this condition seventeen days after he entered the service. After a year of treatment in various hospitals, he was finally made to straighten up in two or three minutes, which to some of us proved that he was a malingerer. Yet other careful neurologists had found such disturbances in him as hemianesthesia. Therefore, it was difficult for us to label him finally as a malingerer. Dr. Pollock's discussion is very interesting and intelligent. His experience was different from mine in the sense that he dealt with neuroses very soon after combat, whereas the patients we had in Plattsburg approached peace conditions. As he stated, it was the policy of the War Department to return to the United States, at least in the beginning, only the constitutional cases. Therefore it is only natural that there should be in these cases a great many with a psychopathic history. Regarding Dr. Pollock's question as to whether or not the symptoms persisted from the beginning, for it was his thought that there might have been intermissions, this might have been the case, but careful histories showed that in a number of instances the symptoms persisted from the beginning. Undoubtedly the fact that the patients knew that they would not be returned to the front had a beneficial influence in their cure and this was shown in the armistice, for while this did not bring about any great change and there were no spontaneous cures, yet our work became very much easier.

A THERAPEUTIC STUDY, PHARMACOLOGIC AND CLINICAL, OF BENZYL BENZOATE*

DAVID L. MACHT, M.D.

Lecturer in Pharmacology, Johns Hopkins University
Medical Department

BALTIMORE

During the past four years, I have been engaged in an extensive and intensive pharmacologic study of opium, and more especially of the so-called "minor" opium alkaloids, individually and in combination with each other and with the principal opium alkaloid morphin. As the result of this work, it soon became evident that the minor opium alkaloids can and do modify the effects of morphin very markedly when given in combination with it. Thus it was pointed out that there is a distinct difference in the analgesic effect produced by morphin, on the one hand, and by opium, on the other, because of the presence of the minor alkaloids in the latter.¹ Again, important differences have been shown to exist for the same reason between the pharmacologic action of morphin and opium on

the respiratory center,² the vomiting center,³ and other centers in the medulla.

EFFECTS OF OPIUM ALKALOIDS ON SMOOTH MUSCLE

One interesting feature disclosed by the pharmacologic studies just mentioned is the fact that while opium and its alkaloids exert their most marked effects on the central nervous system, nevertheless they produce also distinct and important pharmacologic effects on peripheral structures, and more particularly on smooth muscle organs. I first studied the action of the opium alkaloids on smooth muscle in connection with a pharmacologic study of the ureter,⁴ because excised rings of that organ permit of an accurate analysis of the action of drugs on the rhythmic contractions or peristaltic movements and the tonicity of smooth muscle. It was soon established from studies on excised ureters of lower animals and of man as well as from observations of the ureters in lower animals *in situ*, that the opium alkaloids in respect to their action on those organs can be divided sharply into two classes: the pyridin-phenanthrene group, of which morphin is the principal member, on the one hand, and the benzyl-isquinolin group, of which papaverin is the principal representative, on the other. The morphin group was found to stimulate the contractions of the ureteral preparations and increase their tonicity, while all the members of the papaverin group were found to inhibit the contractions of the ureters and lower their tonus.

It was found, furthermore, that in combinations of members of the two groups, small amounts of the benzyl-isquinolin class were sufficient to overcome the stimulating effects of the morphin group. These observations led to several practical deductions. Thus, at my suggestion, Dr. J. T. Geraghty injected a solution of papaverin directly into the ureter of a patient and in that way facilitated the expulsion of a small ureteral calculus.⁵ Again, the tonus-lowering action of papaverin and its relatives gives a scientific explanation for the well-known empiric observation that opium is more efficient in relieving the pains of renal colic than is morphin when given alone, because, when the combination of total opium alkaloids is administered, the patient has the advantage of both the central narcotic or analgesic effect of morphin as well as of the peripheral tonus-lowering or antispasmodic influence of the papaverin group.

Following the studies of the effects of the opium alkaloids on the smooth muscle of the ureter, I investigated the action of the same alkaloids on other kinds of smooth muscle. The results of these investigations have been published elsewhere.⁶ The smooth muscle structures thus studied were the intestine, pyloric rings, uterus, gallbladder, urinary bladder, biliary ducts, seminal vesicles, vas deferens, bronchial rings, and rings of excised arteries. As a result of these investigations, I was led to conclude that the action of the opium alkaloids on all kinds of smooth muscle structures is the same as that described in connection with the ureter, namely, that the morphin alkaloids stimulate contractions and increase tonus, while the papaverin alkaloids inhibit contractions and lower tonicity, and, furthermore, that so far as the peripheral

effect is concerned, in case of combinations of the two groups, the benzyl-isoquinolin constituents exert the predominating effect. Here, again, some practical deductions were drawn from the experimental data. Thus it was found, as has been long known by empiric observation, that opium is more efficient in relieving gallstone colic and uterine colic than is morphin when administered alone.

Following the experimental investigations just described, I undertook a further analysis of the interesting peripheral action of the opium alkaloids on smooth muscle. The results of these investigations have been published before. Briefly stated, the conclusions to which these studies have led were that the stimulating effect of the pyridin-phenanthrene group of alkaloids is to be attributed to the pyridin portion of their molecules, while the inhibitory and tonus-lowering action of papaverin and the other members of the benzyl-isoquinolin group are to be ascribed to the presence of the benzyl grouping in their molecules. The reasons for these conclusions are to be found explained in detail in a previous article.⁷

EFFECT OF NONALKALOIDAL AND NONNARCOTIC COMPOUNDS

These observations and conclusions led me to surmise that possibly the inhibitory and tonus-lowering effects of papaverin might be produced by the exhibition of a benzyl grouping in some simpler form. Accordingly, a search was made for simple non-alkaloidal and nonnarcotic compounds containing the benzyl radical which could be administered to animals without toxic results. Two such bodies were discovered. They are the well-known esters benzyl benzoate and benzyl acetate. As these esters are practically insoluble in water, their pharmacologic action could not be well studied on excised tissues or isolated organs; but experiments with them on intact animals revealed the fact that both of these esters actually produced the same pharmacologic effects as those of the opium alkaloid papaverin, and that they were much less toxic than papaverin. Metabolic studies in connection with these experiments showed that the benzyl group of benzyl benzoate and benzyl acetate is, in a large measure, converted in the body into hippuric acid and is excreted as such in the urine, and also in the saliva, bile and pancreatic juice. The comparatively very low toxicity of benzyl benzoate and of benzyl acetate for animals, and their striking papaverin-like effects on various viscera, led me to try their action on myself, and as no untoward or even disagreeable symptoms followed the ingestion of these drugs by mouth, it was deemed justifiable to administer these agents to suitable patients with their consent.

The conditions in which it was anticipated that the benzyl effect would tend to produce therapeutic results were those either of excessive peristalsis or excessive spasm of smooth muscle.⁸ It would take too much time in this communication to describe in detail all the cases in which the benzyl esters were administered. I need only state that for oral administration the benzoate was chiefly used, as the acetate, owing to its sharp, fruity, banana-like odor, is liable to disagree with many stomachs. The benzoate was administered either in the form of an alcoholic solution or, dissolved in oil, in

the form of capsules. Occasionally, intramuscular injections were also employed, in which case both the benzyl benzoate and the benzyl acetate were given in oil.

CLINICAL CONDITIONS TREATED WITH BENEFIT

The clinical conditions in which the benzyl esters were given and in which their administration was followed by remarkable pharmacologic and therapeutic results can be summarized as those of:

1. Excessive peristalsis of the intestine, such as in diarrhea and dysentery. Here, truly remarkable results were obtained. Diarrheas of long standing, both in young and in old persons, were quickly checked by a brief employment of benzyl benzoate by mouth; and even in cases of dysentery also, patients were greatly benefited by it. A series of dysentery cases has been studied for me by Professor Haughwout of the University of the Philippines, with most remarkable success, and is reported by that author elsewhere.⁹

2. Intestinal colic and enterospasm, both of a post-operative and other character.

3. Pylorospasm, whether of functional character or produced reflexly by ulcers and neoplasms. In these cases the effects of the drug could be and were studied by the roentgen-ray method.

4. Spastic constipation, in which there was a tonic spastic condition of the intestine. This was relaxed by the antispasmodic action of the benzyl radical and the condition relieved.

5. Biliary colic. In a number of cases of gallstone colic, patients were treated very successfully with benzyl benzoate.

6. Ureteral or renal colic. I have collected records of a number of such cases in which patients were treated with the benzyl esters with very good results.

7. Vesical spasm of the urinary bladder. Here also, a number of patients with these affections were treated with remarkable results.

8. Spasmodic pains originating from the contractions of the seminal vesicles. At least two cases have been found in which patients had such pains, in both of which great relief was experienced after the administration of benzyl benzoate.

9. Uterine colic. I have a record of a large number of cases of spasmodic dysmenorrhea, in which treatment by other drugs, by pessaries and even by curettage was unsuccessful, in which complete relief was obtained after one or two doses of benzyl benzoate by mouth.

10. Arterial spasm. Under this heading I include a large number of cases of hypertension or high pressure. It was found that the administration of benzyl benzoate by mouth markedly lowered the blood pressure, both the systolic and the diastolic, the effect, in practically all such cases, being more lasting than that produced by the administration of nitrites. Indeed, patients who did not respond to the nitric treatment often responded with a falling blood pressure after administration of benzyl benzoate. I have been giving benzyl benzoate by mouth to a large number of nephritides over long periods of time. No deleterious effects on the kidney function have been noted in any of these; the hypertension, however, has been greatly improved in most of them. The effect of the benzyl

Macht, D. L. J. Pharmacol. & Exper. Ther. p. 141-170 (July 1918).

Macht, D. L. Proc. Soc. Exper. Biol. & Med. 15, 7-10 (1919).

Haughwout, F. C., Lantz, P. T., and Asanuma, M. A.: Pharmacologic and Clinical Studies on the Treatment of Proctocolic Dysentery with Benzyl Benzoate. Arch. Int. Med., to be published.

treatment on the arterial wall is seen from the fact that in cases of high blood pressure benzyl treatment produces a fall, not only in the systolic but also in the diastolic readings. Thus, for example, in one case, after the administration of benzyl benzoate by mouth, the blood pressure fell from 200-140 to 180-115; in another, from 320-160 to 255-140; in another, 194-100 to 178-80, and in another, from 215-145 to 190-135. A number of cases of coronary spasm (angina pectoris) seemed to be benefited by the benzyl treatment.

11. Cases of bronchial spasm. It was found that benzyl benzoate was capable also of producing relaxation of the bronchial spasm in patients suffering from true asthma. As the term asthma is applied to a large variety of conditions, and even bronchial asthma is etiologically not a single entity but is produced by a great many factors, it was natural to find that not all cases of asthma responded to the treatment. It may be stated, however, that wherever there were signs of bronchial constriction or spasm, benzyl therapy produced relief in almost every case. I collected records of at least 200 such cases. A fuller paper on the subject is published elsewhere.¹⁰

While the indications for the exhibition or administration of the benzyl esters, as described above, are manifold, it will be seen that the rationale of the treatment in all the cases is fundamentally one and the same, namely, that it is due to the inhibitory and tonus-lowering or spasm-relaxing action of the benzyl radical on smooth muscle. A complete pharmacologic study of the benzyl esters, with further therapeutic observations, was published in the *Journal of Pharmacology and Experimental Therapeutics* for June and July, 1918. Since the publication of those papers, I have collected a great deal of additional data, both in Baltimore and from different parts of the United States and abroad, which have fully corroborated the original findings and, indeed, have exceeded my expectations.¹¹

ABSTRACT OF DISCUSSION

DR. DOUGLAS VANDERHOOF, Richmond, Va.: Would you use this drug in hiccup?

DR. DAVID I. MACHT: I would not. Our perfection of it is not that far advanced.

DR. W. A. BASTEDO, New York: Dr. Macht, is the dose in drops? Has it abolished peristalsis in the alimentary tract?

DR. DAVID I. MACHT: It does not abolish peristalsis completely. The only case of this kind that I had was in a child, and the patient got well. In regard to the dose, I meant drops.

The Changing World.—One of the signs of the times is that Arthur Schnitzler's "Professor Bernhadi" has recently been having a run at a theater in Vienna. It was published in book form several years ago but the censor would never allow it to be given on the stage as it portrays the conflict between the priest, who insists on the religious rites for the dying, while the physician tries to save the patient—who does not know that he is dying—the anguish of the knowledge of this fact. The play brings in fifteen physicians. Schnitzler is the son of a Vienna physician and first studied medicine, graduating in 1885 and holding the post of second physician to the General Hospital in Vienna from 1886 to 1888. The *Fortnightly Review* once said of him, "No dramatist has written tragedy with so light a hand or comedy with so ironically pathetic a smile as Arthur Schnitzler."

THE USE OF BENZYL BENZOATE IN DYSMENORRHEA*

JENNINGS C. LITZENBERG, B.S., M.D.

MINNEAPOLIS

It requires no little temerity to favor the addition of another drug to the already too lengthy list of medicines used for the relief of dysmenorrhea, but the logic of Macht's paper¹ recommending the use of benzyl benzoate in all painful spasmodic conditions of smooth muscle organs was too compelling to be resisted. Therefore, when my attention was called to this article by my colleague, Professor Hirschfelder, we determined to make a clinical study of this new antispasmodic, or rather this newly discovered action of a well known substance. This study is not based on the general run of cases as they come in private and dispensary practice, but on cases deliberately selected from among college women and nurses, because of their high intelligence and ability to cooperate in following directions and answering necessary questions under circumstances known to be experimental.

This so-called minor gynecologic condition has great import because of its frequent occurrence, its economic influence, its unknown etiology and the very unsatisfactory results of its treatment. Tabler and Engelman (Block)² say that from 50 to 80 per cent. of American girls suffer from dysmenorrhea. Be the percentages what they may, there is scarcely a school, store, office, factory or home that is not interfered with on account of young women being either reduced in efficiency or entirely incapacitated.

CLASSIFICATION OF DYSMENORRHEA

Of the etiology of dysmenorrhea we know little, and none of the many theories has been incontrovertibly established; although the following classification of Block,³ based on theories of cause, comes nearer being really logical than most others:

1. Obstructive. These cases are usually operative.
2. Ovarian, due to an increase of ovarian secretion; treated by inhibiting the hyperactivity of the ovary by cocaineizing or cauterizing the "genital spots" on the nasal septum or by neutralizing the excessive secretion with epinephrin.

3. Vagotonic, due to irritability or increased tonus of the autonomic nervous system. This type is usually called spasmodic, or essential dysmenorrhea; treated by an antispasmodic like atropin which diminishes the irritability of the autonomic nerves, thereby relaxing the uterine musculature, thus relieving the colic.

The pelvic division of the autonomic system supplies the uterus, and there are also fibers from the antagonistic sympathetic system.

In women with vagotonia, which is an increased irritability of the autonomic system, the uterus is spastic; the control by the sympathetics having been in some way overbalanced so that at the menstrual period spasmodic or essential dysmenorrhea results.

VALUE AND EFFECT OF ATROPIN CONTRASTED
WITH THAT OF BENZYL BENZOATE

As atropin paralyzes the autonomic group, it is a logical treatment for this type of painful menstruation.

Novak of Baltimore⁴ called attention to the atropin treatment and reported good results in about thirty cases and he quoted Novak of Vienna,⁵ who had used it for many years.

For some time I have used atropin in doses of from $\frac{1}{150}$ grain to $\frac{1}{50}$ grain, according to the severity of the attack, with very satisfactory results; but I must confess to a reluctance to use it extensively because it is too potent a drug to place in the hands of every patient fourteen times a year and, furthermore, it frequently must be given in dysmenorrhea to the point of tolerance in order to get the desired antispasmodic effect.

The favorable reports on the use of atropin, the logical basis for its use and the good results obtained convinced me that an antispasmodic was certainly indicated in essential or spasmodic dysmenorrhea, which conclusions prepared me for a ready acceptance, for trial at least, of the benzyl esters as antispasmodics in place of atropin.

Macht showed by animal experiments and clinical trial that benzyl benzoate had the same antispasmodic action on smooth muscle organs as certain opium alkaloids of the papaverin type, this action being due to the benzyl component of the molecule in these substances; benzyl benzoate, however, having the advantage of being practically nontoxic.

Atropin produces its antispasmodic effect by paralyzing the autonomic nerves supplying unstriated muscle, but the benzyl esters seem to act *only on the muscle cell itself*.

Macht tried benzyl benzoate with beneficial results in gastro-intestinal colic, renal and ureteral spasm, biliary colic, dysmenorrhea, angiopeptic conditions and bronchial spasm. He reports 300 cases, in some of which benzyl benzoate was continued over long periods with no dangerous or toxic symptoms.

SIZE OF BENZOATE DOSE

Macht used a 20 per cent. alcoholic solution of the drug flavored with some carminative, giving a dose of from 10 to 30 drops in cold water.

Our first patients complained bitterly of the unpleasantness of this solution, especially the aftertaste, so Professor Hirschfelder made up a 20 per cent. emulsion with acacia in aromatic elixir of eriodictyon which proved a much more pleasant medicine to take.

In dysmenorrhea we did not get quite as complete relief as desired with the dosage recommended by Macht, so we increased the dose to 1 teaspoonful and finally to 2 drams given every two hours. We observed no bad effects from this greatly increased amount, unless an occasional case of vomiting and rarely a feeling of weakness might be so attributed. We used several other preparations, but none of them were as pleasant to take as the emulsion in elixir of eriodictyon.

We shall endeavor in our future study to determine the minimum dose required and the best method of giving it.

SUMMARY REPORT OF CASES

Of forty-three patients there were thirty-five, or 81.3 per cent., who were relieved of pain. In twenty-seven cases, or 62.7 per cent., the pain was completely stopped, and in eight cases, or 18.5 per cent., the suffering was greatly relieved but not entirely eliminated.

In two cases, or 4.6 per cent., the pain was somewhat relieved, but to no great extent.

In six cases, or 13.9 per cent., there was no benefit whatever.

This study will continue as originally intended over a long period so that the volume of cases and repeated trials may give us sufficient basis for final conclusions; but the early results were so striking that we thought a preliminary report should be made in order that the value of benzyl benzoate might be tried out by the profession at large.

We hope that the promise of this drug may lead many physicians to try it and that we may soon have numerous reports, for it is only by an analysis of a very large number of cases that we can determine the real value, and fix the limitations of benzyl benzoate as an antispasmodic in painful menstruation.

PATIENTS' TESTIMONIES

The most striking sidelight encountered was the answer to the question, "Does menstruation interfere with your usual duties?" Thirty-five, or 81.3 per cent., answered in the affirmative. To the question, "Must you go to bed?" twenty-nine, or 67 per cent., said they were compelled to do so, illustrating the economic value to be obtained by the relief of dysmenorrhea, to say nothing of the human suffering.

Thirty-three patients, or 76.7 per cent., had tried other treatment, but only eight, or 24.2 per cent., had obtained any relief. One of these I had dilated with absolutely no relief; however, one dose of benzyl benzoate stopped her pain entirely.

Fifteen cases were completely relieved of pain after one dose (2 teaspoonfuls of a 20 per cent. emulsion); twelve, after two doses at two hour intervals; one required three doses and one four doses and one five doses; those who obtained no relief took from two to six doses.

Other symptoms, headache, backache, etc., were not uniformly benefited.

The testimony of the patient in a condition like this is the only thing we have to go by in determining its efficacy; therefore a few statements by these young women will not be out of place. One said she could carry on her work with less difficulty and discomfort than usual, saying that "it took away that awfully oppressive feeling, and interference with duties was less in quantity and duration," and her headaches were much relieved.

Another, Patient 7, asserted that she "was relieved entirely after the second dose and was able to eat during the first twenty-four hours," which she had been unable to do for several years.

Patient 13 was a woman, aged 40, with acute gonorrhea accompanied by cramps throughout the pelvis, which had lasted for two weeks. She was completely relieved after one dose.

Patient 16 said that after taking the medicine she "could do a good day's work, and life was worth living."

⁴ Novak, I. G. The Atropin Treatment of Dysmenorrhea. J. A. M. A. 64:141 (Jan. 29) 1915.
⁵ Novak, I. W. Klin. Wochenschr. 26:3 (1) 1913.

Patient 20 averred that for the first time she was not compelled to go to bed, and that the usual faintness and weakness were absent.

Patient 29 was one of the few persons not within the class of college women and nurses especially selected for study. She was a forewoman in an iron factory, compelled to be on her feet all day; but after taking the benzyl benzoate she was "able to keep working throughout the menstruation, which had never happened before."

RESULTS IN ESSENTIAL DYSMENORRHEA

We have obtained excellent results in all three of the classes set forth by Block: namely, obstructive, ovarian and vagotonic or spasmodic dysmenorrhea, and we also have had favorable reports in the so-called acquired type due to some demonstrable pelvic pathologic condition and even in the inflammatory type.

However, the most reliable results were obtained in the spasmodic type or essential dysmenorrhea, where benzyl benzoate has a distinct advantage over atropin, on account of its very low toxicity; furthermore, there are no drugs other than atropin and morphin which give so much promise of relief. Morphin we dare not use; and if we have a nontoxic anti-spasmodic, it should certainly replace atropin, which is not entirely devoid of danger.

To be sure, benzyl benzoate only relieves a symptom and does not get at the underlying cause of painful menstruation; but dysmenorrhea is only a symptom after all, so until we have solved the problem of the etiology of painful menstruation we must continue to aim our shafts at the symptom. Wherever a cause can be found, of course, it should be removed; any pathologic condition of the pelvis must be corrected; but antelection of the uterus as a real cause of obstruction is very doubtful in spite of the fact that many patients are relieved by dilatation. Far too many cervixes are dilated.

Benzyl benzoate should be tried before dilatation or other pelvic operations are advised; and if it eventually proves to have the value it promises, many a woman will be saved an operation and more women will seek relief if surgery is not the only avenue of escape from suffering.

If this drug, in the final analysis, fulfils its promise, the sum of human suffering will be greatly reduced and a great economic asset acquired.

The prescription used is given herewith.

	Gm.
R. Benzyl benzoate	10
Mucilage of acacia	5
Aromatic elixir of erythron	35
Give from one-half to 2 teaspoonfuls, according to necessity.	

CONCLUSIONS

1. The cause of dysmenorrhea is still unsettled.
2. The treatment has been unsatisfactory.
3. Antispasmodics are logically indicated, for in spite of doubtful etiology the painful spasm of the uterine muscle is incontrovertible.
4. Benzyl benzoate has an antispasmodic action and is practically nontoxic, which gives it preference over atropin.
5. This series is too small to permit conclusions, but is given for what it may be worth. Of the forty-three cases presented, in 81.3 per cent. the patients were relieved of painful menstruation.
6. Pain was absolutely eliminated in 62.7 per cent.
7. Pain was greatly relieved in 18.5 per cent.

8. Pain was slightly benefited in 4.6 per cent.

9. Pain was not relieved at all in 13.9 per cent.

10. These results, while not conclusive, warrant a thorough test, by the profession, of the value of benzyl benzoate in dysmenorrhea.

119 Institute of Anatomy, University of Minnesota.

ABSTRACT OF DISCUSSION

DR. EMIL NOVAK, Baltimore: While we do not know the cause of spasmodic dysmenorrhea, it seems fairly certain that the actual pain in these cases is due to spasmodic contraction of the uterine musculature. The logical symptomatic treatment, therefore, is the use of antispasmodic drugs. The two drugs which are most efficacious as antidysemorrhoeics are the very two which should not be used, morphin and alcohol. Aside from these two, the drug which has in my hands been most valuable is atropin, to which Dr. Litzenberg has alluded in his paper. The general effect of benzyl benzoate would seem to be similar to that of atropin, and, if it is much less toxic than the latter, it would seem to be preferable to it. Such drug treatment of dysmenorrhea, however, is, after all, only a makeshift, and we should continue our effort to achieve a more rational therapy, which, I am convinced, will be along the lines of organotherapy. In practically all of these cases the uterus is the seat of defective development, in some cases very marked, in other cases slight. It is interesting to note that where the anatomic defect is least conspicuous, that is, in the so-called subpubescent cases, the dysmenorrhea is apt to be most severe, as I emphasized in a paper presented before this section last year. These developmental disorders are undoubtedly due to endocrine disorders which as yet are not well understood, but the problem is sure to be worked out sooner or later. Until this is done, the only course left for us in the management of these cases is the makeshift treatment of drugs, and the remedy advocated by Dr. Litzenberg should, therefore, constitute a valuable addition to our armamentarium.

DR. J. C. LITZENBERG, Minneapolis: I believe with Dr. Novak that we should not shirk treatment just because we have not found the cause of the condition. Neither should the obtaining of relief for pain lead us to relax our efforts to find the cause. Of course, our remedies are makeshifts. We can aim at the symptom because we do not know the cause. The use of epinephrin is along the line of counteracting the ovarian type of dysmenorrhea. The profession generally neglects the ordinary means of treating dysmenorrhea. The superintendent of the University Hospital told me that more than 50 per cent. of the nurses lose their dysmenorrhea when they get on the floors of the hospital. The physical exercise, interest in their work and the hygienic living correct a large part of the difficulty. In the treatment of this condition, physical exercise and hygienic treatment are neglected. The majority of young women do not come for treatment. Many suffer in the privacy of their own homes because of innate modesty or because of their desire to play the game of womanhood bravely. They get a prescription, not a study, and I want to emphasize the idea of study brought out by Dr. Novak. The cases should be classified and treated according to the class in which they may fall. Of course, this is only a theoretical classification, but if they are studied and the hygienic measures alone are used one half of these women would be relieved. In those cases with very great pain, this newly discovered action of a well known substance certainly ought to be used because it is a substitute for three dangerous drugs—morphin, alcohol and atropin.

Child Welfare.—Juvenile courts occasionally have to deal with cases where delinquency is just the result of a spirit of adventure. The child is starved for something that appeals to his imagination. Neither home nor school makes provision for this necessary element in human experience, so the young adventurer seeks it himself on nocturnal journeys. — *School Life* 2:2 (May 16), 1919.

FATALITIES IN HOSPITALS CAUSED BY PATIENTS FALLING FROM WINDOWS

FROM THE RECORDS OF THE CORONER'S OFFICE,
COOK COUNTY, ILLINOIS *

EDWARD H. HATTON, M.D.
CHICAGO

Fatal results ensuing from patients of hospitals and sanatoriums falling or jumping from windows are of such frequent occurrence in Cook County, Illinois, that the matter is deserving of attention, with a view to ascertaining the causes and providing a remedy. Between the beginning of the year 1907 and the end of 1918, there are forty-nine such deaths recorded in the coroner's office. Thirty-one different hospitals are concerned, and ten of the forty-nine patients so killed were in public institutions, that is, those under the control of the city, county or state.

Twenty hospitals had only one such death each, eight had two, two had three, and in one large hospital there were seven. In the nine years 1907 to 1916 there were twenty-six deaths so recorded, an average of nearly three a year, and the largest number for any one year in that period was five in 1908. Again, in 1916 there were five deaths; in 1917, eight, and in 1918, ten.

MULTIPLE CASES IN CERTAIN HOSPITALS

It is noteworthy from the foregoing that one such death has not prevented repetitions, for in eleven hospitals more than one has occurred in the same year in three instances, and in two others within less than two years. In the last three years there has been a tendency for the number to increase, partly because the hospitals are becoming larger and the number of used beds is steadily growing. Other reasons perhaps are the decrease in the number of interns, nurses and attendants, and a falling off in efficiency, as the results of war activities.

In Table 1 these accidents are grouped according to the situations that seem most prone to lead to such catastrophes. All were adults; thirty-four were men, fifteen were women.

TABLE 1—STATISTICAL DATA

	No.
Patients in private rooms at time of accident	75
Patients in wards at time of accident	19
Patients with suicidal impulses	8
Patients with attendants present when accident occurred	4
Patients with delirium previous to accident	11
Patients who had previously attempted self violence	5
Patients under mechanical restraint from which they escaped	1
Native-born patients (excluding Canadian)	13
Foreign-born patients	24

CONDITIONS AS THEY OBTAIN

The height of the window sills varied from 2 to 5 feet from the floor. In some instances the windows were open, in others closed; and in some cases not only were the windows closed and fastened, but the screens were in place with fixed attachments. The patients then unfastened windows and screens or threw themselves through the glass and screen. With attendants or nurses in charge, they sometimes took advantage of their temporary absence from the room.

In one case a male patient held off two interns and two nurses with a chair used as a weapon until he could smash the window and effect his escape. In another instance the attendant's cot was placed in front of the door, but the man made his escape across this cot into the corridor and thence to an open window and a fire escape from which he fell to the ground. Foreigners are much more given to trying to make such escapes from hospitals than the native born, especially when delirious, probably because of the strangeness of their surroundings and the absence of attendants of their own race who speak their language. Two patients made their way to fire escapes, and the accidents occurred in connection with the openings provided for fire emergencies. Three men went to toilet rooms and made their way out of windows in those rooms.

TIME OF OCCURRENCE OF FATALITIES

It is also important that three fifths of these deaths have taken place in the afternoon and the first half of the night. More accidents occurred between the hours of 9 and 10 p. m. than at any other time of the day. It seems fair to relate this to the daily activities of the hospitals. Most of the hospital work is crowded into the forenoon and the early afternoon; there are more nurses on duty; this is the time that the majority of the attending men chose for their rounds; opportunities for escape are remote. On the other hand, after midnight the hospital quiets down and most of the patients are asleep. The external stimuli are reduced to a minimum. Even delirious patients are quiet.

TABLE 2—CLINICAL DIAGNOSIS OF THE DISEASES FOR WHICH THE PATIENTS WERE HOSPITALIZED

	No.		No.
Alcoholism	9	General paresis	2
Melancholia	5	Pyropticism	2
Postoperative delirium	3	Tuberculosis	1
Heart disease	3	Burns	1
Sensory	3	Prostatic hypertrophy	1
Suicidal mania	4	Polio	1
Pneumonia	4	Vagrose ulcer	1
Acute nephritis	2	Old age	1

TYPES OF PATIENTS CONCERNED

In this variety of diseases, two types of patients are prominent: Those in whom there is a tendency to delirium, and those in whom there is some mental derangement or on which discouragement weighs heavily because the prognosis is bad. Patients suffering from influenza and the attendant bronchopneumonia seem particularly liable to mental derangement or delirium which may result disastrously in this way. Delirium tremens and melancholia are also conspicuous.

PREVENTIVE MEASURES

It may be that greater care and especially more aggressive action in the face of emergencies would have prevented some of these accidents. Yet many of them were unavoidable except by removal of access to the windows or the possibility of breaking through them. The use of bars or gratings has been objected to on the ground of its being offensive to the patient or from the standpoint of the practical management of hospital affairs; that is, because of hindrance in the washing of windows, blocking of entrances to fire escapes, and interference with ventilation or the attachment of screens. It is with the improvement of such details of hospital construction that the pre-

* This article was suggested and the statements are authorized by Peter M. Hoffman, coroner.

vention of such deaths will be attained most effectually, and this report is made with the hope that with full realization of the need, serious consideration of such details will be undertaken, for to a large degree such deaths are preventable.

CONCLUSIONS

In view of the facts as stated these conclusions seem justified:

1. A concerted effort should be made toward designing a standard hospital window and screen which would absolutely prevent such accidents from occurring and yet be satisfactory from the mechanical standpoint, as regards convenience in washing, use of fire escape, ventilation and lighting.
2. Nurses and attendants, especially those on duty during the afternoon and the first half of the night, should be continually warned of the possibility of such accidents occurring and should be prepared to act quickly and wisely in emergencies.
3. Every toilet room used by patients should be protected by bars or gratings across the windows.
4. Special precautions should be taken not only as regards those who are actually delirious but also with respect to others who from the nature of their sickness may become delirious.
5. With regard to foreigners as patients an effort should be made to have with them, from time to time, if not regular attendants, at least others who speak their language.

MASTOIDECTOMY

POSTOPERATIVE TREATMENT BY USE OF SURGICAL
SOLUTION OF CHLORINATED SODA AND MODI-
FICATION NECESSARY TO SECURE THE
BEST RESULTS *

JOHN B. POTTS, M.D.

OMAHA

This paper is not given as an original contribution, but as an adaptation of the Carrel-Dakin treatment to postoperative mastoid wounds.

There are several methods of closing the wound after a mastoidectomy. This very fact is evidence that we have not as yet an entirely satisfactory method, and I am taking the liberty of presenting this method to the section in the hope that it or some modification of it may aid in a solution of our difficulties.

The ideal we are striving for is for a method that will fulfil the following conditions:

1. The maximum safety for the patient.
2. The minimum time of convalescence.
3. The minimum deformity.

AUTHOR'S METHOD

In order that any method of closing the mastoid wound may be uniformly successful, a thorough mastoidectomy must be done. Considering now that this operation has been done, a Carrel Dakin tube is placed in the excavated mastoid cavity, starting at the tip of the mastoid and having its exit at the upper angle of the wound. A second tube is adjusted so that it lies in the opening of the antrum and has its exit in the lower angle of the wound. These tubes are brought

forward and upward and fastened with a strip of adhesive plaster to a point on the temporal region of the forehead. The wound is closed with the usual catgut sutures, care being taken to carry them through all the layers of tissue. It is well not to place the stitches closer than three-sixteenths inch to each angle of the wound in order that a little space may be left for drainage around each tube. This precaution adds greatly to the comfort of the patient at the time of irrigation. A small sponge is placed directly over the mastoid cavity and pressed down firmly so as to obliterate as much dead space as possible. A cotton pack about 8 inches square enclosed in gauze is placed over the ear, and the head is bandaged in the usual way. It is very essential for the comfort of the patient that the cotton pack be sufficiently thick to absorb all the moisture from the irrigations. In applying the bandage, from one-half inch to 2 inches of the tubing is left free. These ends are wrapped in sterile gauze, and care should be taken that they be kept sterile.

Irrigations are begun at once with a properly prepared and carefully titrated surgical solution of chlorinated soda (Carrel-Dakin solution) about 1 ounce to each tube every two hours. The dressings are replaced every twenty-four hours. The condition of the wound and discharge governs the frequency and amount of solution to be used during the ensuing twenty-four hours. Ordinarily no change is made in the orders for the first two days. After this the irrigation is continued every two hours during the day, but the night period is extended to four hours. As the secretion decreases, the frequency of irrigation is diminished. Usually in from four to eight days the wound is sterile. If one has access to a laboratory, this can be ascertained by removing one of the tubes and taking a culture by the ordinary method with a platinum loop. If the laboratory is not available, one will have to use his judgment and be guided by the appearance of the wound, and the amount and character of the secretion. The latter when sterile is of a serous nature and should only slightly stain the dressing. I have frequently found it unnecessary to retain both tubes longer than three days. The upper tube was then removed, the lower being retained as it better facilitated drainage. In some cases after four or five days the secretion instead of diminishing became more or less profuse and of a thick, slimy consistency and brownish color. When this occurred, I removed both tubes, cleansed them thoroughly, resterilized, and before reintroducing them thoroughly cleansed the wound with a hot saturated solution of boric acid or hydrogen peroxid. The tubes were then introduced to their original positions and a solution of mercuric chlorid 1:5,000 used in the same manner as the Carrel-Dakin for a twenty-four hour period. In some cases it was necessary to repeat the mercuric chlorid for two or three twenty-four hour periods. When using the mercuric chlorid I always protect the skin by covering it with a layer of gauze saturated with zinc oxid ointment. This protection was necessary also in some cases as a protection from the Carrel-Dakin solution.

In performing the operation we found it an advantage not to extend the incision upward into the temporal muscle. In those cases in which the temporal muscle was injured, there was liable to be some edema over that area.

Following the removal of the tubes, in cases in which there has been a large mastoid there is sometimes an

* Read before the Section on Laryngology, Otology and Rhinology at the Seventeenth Annual Session of the American Medical Association, Atlantic City, N. J., June, 1919.

accumulation of fluid. When this occurred, we thought it was an advantage to cleanse the cavity once daily with a hot saturated solution of boric acid.

The irrigation with the Carrel-Dakin solution had one advantage which we had not anticipated. The solution passed through the antrum into the middle ear and out through the membrana tympani, thus cleansing and sterilizing this tract.

The stitches were usually removed on the sixth day. In order that the cavity may not be infected by extraneous bacteria, it is necessary that the nurse exercise great care in her asepsis when giving the irrigations.

RESULTS

In a series of fifty cases in which we kept accurate data in the University of Nebraska Red Cross Base Hospital 49, Allerey Hospital Center, France, the average time in which the wound became sterile and the tubes could be removed was 9.35 days. All secretions had ceased and the wound was entirely healed in most of these cases by the fourteenth day, and none longer than the eighteenth day. The shortest time in which the tubes were removed was four days and the longest time was eighteen days. The discharge from the external auditory canal ceased in from one to twenty-one days.

COMPLICATIONS

One patient had marked swelling, and the stitches were removed on the second day. This was an early case in the series and did not have sufficient irrigation.

One patient developed infection of the neck below the mastoid.

ADVANTAGES

The principal advantages this mode of treatment has are:

1. It enables the operator to close his wound and still feel that he has as perfect drainage as it is possible to secure.
2. Exposure of the sinus or dura is no contraindication to closing the wound.
3. The ultimate result is a smooth, clean scar without depression.

ABSTRACT OF DISCUSSION

DR. EWING W. DAY, Pittsburgh: At different times different methods have been brought forth to produce rapid healing of the mastoid. We all remember the blood clot, its failure was the inability to obtain a sterile cavity. Anything that will produce a sterile cavity will bring quicker healing. The surgical solution of chlorinated soda is one of the best. Shortly after this solution was introduced in Europe, the Carnegie Steel Company sent Dr. W. O'Neill, chairman, the chief surgeon of that company, to Europe to study this method. On his return we tried it out in the eye and ear Hospital to a considerable extent and found it to be safer and quicker than any other. Some patients complain of the irritating influence of the solution on the skin, and especially the external auditory canal, for some of the solution will get through in spite of gauze shields and ointments. Since my return home I have adopted a slightly different procedure. I never like to quite close a mastoid until it is sterile, although I do have free drainage. Instead of using the surgical solution of chlorinated soda immediately after an operation I pack the wound rather tightly with a piece of gauze which has been saturated in a 35 per cent. tincture of iodine. The next morning I commence cleansing the wound every four hours, using a good green soap and washing it out and drying it thoroughly and redressing it. Do this every four hours during the day. Beginning on the third day, I take cultures to see when

the wound is sterile. As soon as the wound is sterile, close it by freshening the edges of the wound, which can be done quickly, elevate the flaps a little and let the blood run in; close it with metal clamps, and your work is practically done. Within a few days I send the patient home, and he reports back in one week. I have had complete closure and practically healing of the wound in fourteen days. It is utilizing the blood clot, which I formerly opposed, but using it in a sterile cavity. You can follow the same procedure if you do not want to do the primary suture. You can do it without cocaine, the patient does not mind it, and the results have been good in my cases.

DR. ARTHUR C. STOKES, Omaha: I was chief of the surgical service in Base Hospital No. 49 during the time in which Dr. Potts was engaged in this work at Allerey, France. His results seemed to be phenomenal. I had been accustomed in my general observation to see cases go on weeks discharging and granulating and finally healing with large and ugly scars. These cases did not do this. The tubes were put in as the doctor has described and the wound closed. It healed in three or four days and the patients were walking around the hospital. One point the doctor did not mention, and that is, that instead of using petrolatum for his protecting ointment around the wound, he used zinc oxid on gauze. This seemed to be an improvement on the ordinary method of protecting the skin around the wound. It stuck to the wound better and protected it better. The surgical solution of chlorinated soda certainly does excoriate the skin at times. Of course, the nearer neutral the titration, the less frequently excoriation follows, but the value of the solution, if it has any value, depends on the free chlorine present, and that is bound to irritate at times. We learned that if the solution is of any value at all—I am not discussing that question—it is in cases of acute wounds. I am opposed to packing all kinds of wounds, everywhere and anywhere, with tight gauze, where there is pus, and this method makes packing unnecessary. To pack a wound with pus in it seems to be a bad proposition. In general surgery we do not pack infected wounds with gauze. It has been hard for surgeons to learn that gauze does not drain pus. We have gone through that until we know it does not. One more point is the use of mercuric chlorid. It is interesting to see how after using surgical solution of chlorinated soda for a time and then changing to mercuric chlorid, there was in some cases a very sudden reduction in the bacteriologic count. There must then be certain organisms or relations in wounds in which mercuric chlorid is of more value than surgical solution of chlorinated soda.

DR. FRANCIS P. EMMERSON, Boston: I have been very much interested in this paper. I hoped that in our surgical mastoid work we were getting away from complicated methods to a more simple technic. In any surgical procedure there should be some definite reason for every step we take, and in the mastoid operation the first indication is the removal of diseased tissue and drainage. After you have done a complete and thorough mastoid operation, you pack the cavity to stop bleeding and set up reaction. In the procedure which I have adopted, and which is used in the hospital with which I am connected, we rarely disturb the packing until the fourth day. At the end of the fourth day the packing is removed. After removing the packing we want to keep control of the middle ear until it is dry. A simple drain carried up to the aditus will control the middle ear until it is dry. Then after the middle ear is dry and the aditus has been walled off, there is no danger whatever in letting the whole mastoid cavity close by what you might call a modified blood clot method. In the last series of seven cases in which I operated, the middle ear was dry, with the exception of one case, on the fourth day. That means that the operation has been radical enough to remove the diseased tissue, and that the mastoid cavity is free from necrotic areas. There is no one principle in surgery more important than to let Nature alone when she is doing all right, and to wipe out a cavity when it is granulating normally is bad practice; to irrigate a cavity when it is granulating normally is also bad practice. In fact, to do anything that is meddling when the cavity is in good condition is bad surgery. If you have excessive granulations,

remove them; if you have a septic wound, use surgical solution of chlorinated soda; nothing is better. But if you have done a radical thorough operation and the middle ear is dry, let it alone, unless you know that there is a septic cavity, and if so, the use of the surgical solution of chlorinated soda is one of the best measures that we have at our command.

DR. C. J. SWAN, Evanston, Ill.: In our experience at Camp Wheeler, those mastoids which were found at the operation to contain much pus, where the necrotic process had gone far, were those that healed the most readily. Cases in which operation was done very early and which were infected with streptococci were the cases that continued to suppurate and were slow to heal. They were operated early, the necrotic process had not been delimited, and the patient apparently had not set up a resistance to the infection. On the other hand, cases that had gone far and that we did not see until they had had the mastoid infection for weeks, healed very quickly. We tried the Carrel treatment in ten cases that were sent directly from the operating room to the Carrel treatment ward. We controlled these cases by ten other cases in which we used a treatment similar to the one Dr. Emerson described. We sewed the wound primarily down to about two-thirds of the way with three sets of stitches, one through the pericranium, one through the subcutaneous tissue and then a skin suture. We packed the cavity and left the packing in for three or four days, then removed it, and maybe packed it once or twice more. Healing was accomplished in the favorable cases in a little over two weeks. We had one case, a very necrotic case, that healed in ten days. With the Carrel treatment we had more scar, and the average time of healing was about a week longer. The cases that were suppurating very much did better with this treatment. The favorable cases did better with the simple treatment. In other words, there is no one method of treatment applicable to all cases. Each case should be treated according to the condition presented.

DR. WENDELL C. PHILLIPS, New York: I have been very much impressed with the aggressive work that has been accomplished by Dr. Potts and by those who have taken part in the discussion. But I think there are one or two words of caution that may well be mentioned at this point. Evidently in the case of those who have fallen into the hands of the men who have been doing this operation, their "lines have fallen in pleasant places," because the experiences that some of us have in hospital work in great cities would not bear out the testimony that has been given here today. If the method of treatment that the surgical solution of chlorinated soda offers means the results given in this paper, there is no question that its adoption will be warranted. I do think, however, that if you use it in the ordinary run of cases seen in the large hospitals, the results could not possibly be the same. The word of caution I wish to give is this, that unless the discharge from the external auditory canal ceases entirely after a few hours or days of use of the Carrel treatment, the case should not be reported cured even if the postauricular wound is healed, for otherwise a recurrence may be expected. Closing the posterior wound before the discharge has ceased from the external auditory canal means trouble. A case is cured only when the mastoid is healed and when the discharge has ceased from the external auditory canal, and if the cases reported at this time have not had that course they are not cured. In the care and treatment of patients, a dressing every four hours may be very easy where there are not very many mastoid patients to care for, but if you take them in a hospital where you have from forty to eighty such patients under treatment all the time, postoperative cases, and you dress them every four hours, it will require an increase in the hospital staff, because you cannot trust the nurses to make these dressings, and I can see where there will be an enormous amount of labor.

DR. EDWARD J. BERNSTEIN, Detroit: I would like to add a word of caution about the use of iodine gauze. I used it in one case and in a very short time it set up a meningeal irritation which was not relieved until I took out the gauze. It seems to me we ought to be very cautious about putting iodine solution into mastoid wounds.

DR. JOHN B. POTTS, Omaha: In this series of cases we had an acute *Streptococcus hemolyticus* infection following influenza. We had some cases of fracture of the mastoid following accidents with high explosives. Three cases that had had an old otitis media and which was stirred up again, and we had cases that had been dragging along for weeks and even months. The boys at the front did not stop fighting for a little thing like a running ear; they had to be really hurt. It was very interesting to see how the different cases responded to treatment. The time in which we could get an ear sterile depended somewhat on how long it had been discharging. In some old cases the discharge did not cease as promptly as in acute cases. In answer to Dr. Phillips, I think his criticism is very just. You will find, however, as you develop your technic that you can instruct one or two nurses to carry out this dressing, and it becomes a simple matter. The dressing is only done once in twenty-four hours. In other words, the doctor or intern only sees the patient once in twenty-four hours. The introduction of the surgical solution of chlorinated soda can be done rapidly by the nurse if she is careful. She can go about with a sterile syringe, we use a little gynecologist's syringe, the kind that were shipped in great quantities to France, and it works very well. The dressings do not take really as much time as when done in the other way.

New and Nonofficial Remedies

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

BARBITAL SODIUM (See N. N. R., 1919, p. 83).

Barbital Sodium-Abbott.—A brand of barbital sodium complying with the N. N. R. standards.

Manufactured by the Abbott Laboratories, Chicago, under U. S. patent No. 782,739 (Feb. 14, 1905; expires 1922); by license of the U. S. Federal Trade Commission.

OVARIAN SUBSTANCE-HOLLISTER-WILSON.—The entire, fresh ovaries (including the corpora lutea) of the hog, cleaned, freed from fat, dried and powdered. It contains no diluent or preservative.

Actions and Uses.—See Ovary (New and Nonofficial Remedies, 1919, p. 202).

Dosage.—From 0.06 to 0.2 Gm. (1 to 3 grains).

Manufactured by the Hollister Wilson Laboratories, Chicago. No U. S. patent or trademark.

Ovarian substance Hollister-Wilson is a yellowish powder, having a characteristic odor. It is partially soluble in water.

One part of ovarian substance Hollister-Wilson represents approximately seven parts of the fresh ovary. When incinerated, it yields not more than 7 per cent. of ash.

DESICCATED CORPUS LUTEUM-HOLLISTER-WILSON.—The fresh substance from the corpora lutea of the hog, dried, freed from fat and powdered. It contains no diluent or preservative.

Actions and Uses.—See Ovary (New and Nonofficial Remedies, 1919, p. 202).

Dosage.—From 0.03 to 0.12 Gm. (½ to 2 grains).

Manufactured by the Hollister Wilson Laboratories, Chicago. No U. S. patent or trademark.

Desiccated corpus luteum Hollister-Wilson is a yellowish powder, having a characteristic odor. It is partially soluble in water.

One part of ovarian substance Hollister-Wilson represents approximately 5 parts of the fresh corpus luteum substance. When incinerated, it yields not more than 6 per cent. of ash.

SODIUM PEROXIDE (See N. N. R., 1919, p. 216).

Sodium Dioxide, Dental-R. and H.—A nonproprietary brand of sodium peroxide complying with the N. N. R. standards, but containing at least 90 per cent. of sodium peroxide, and iron not to exceed 0.006 per cent.

Manufactured by Ruessler and Hasslacher Chemical Co., New York. No U. S. patent or trademark.

FATTY ACIDS AS FOODS

When the world war threatened the integrity of the food supplies of a large part of the nations more intimately concerned in the great conflict, both physiologists and economists began to ask what limits of restriction could safely be endured. It is doubtful whether the nutritive needs of man have ever before been considered so critically as they have been since 1914. Proteins and fats and other nutritive ingredients began to be estimated in calories and grams with profound regard for economy of consumption and prevention of unnecessary waste. National committees and international commissions devoted their best energies to the determination of what the safe minima of food allowance for various classes of the populations under consideration might be. It was a time when waste might mean defeat.

With respect to the human requirement for protein there is a considerable body of evidence of both a statistical and experimental character, sufficient at least to serve as a reasonably safe guide to the limits of husbanding this food-stuff. Much less is known with regard to the absolute needs for fats in the physiologic economy of man. Older "standards" regarded about 50 grams, or somewhat less than two ounces a day, as a possible minimum. The Interallied Scientific Commission on Alimentation, at its second meeting at Rome in April, 1918, fixed 75 grams (2½ ounces) as a desirable daily minimum ration of fat.¹

In many of the countries the fat supply became rudely reduced because of two factors which did not militate against it in peace time. The interference with free shipping prevented importations of fat in places where the stock was normally replenished from elsewhere. Then, fats formerly used as foods were diverted to the preparation of glycerol for the manufacture of explosives. What this meant in England can now be authentically stated from a report of the Royal Society's Food (War) Committee.² It is admitted that in the last months of 1917 the marked shortage in the supply of fats led to a reduction of the

fat ration per week per person to about 3½ ounces (as derived from butter, margarin and lard), while the limitation in the meat ration reduced the fat supplied in this way to some 3¼ ounces or less. At most, therefore, even allowing for fat in milk and other food-stuffs, probably only about 7 or 8 ounces per week were available.

When fats are chemically disintegrated by hydrolysis to prepare glycerol, fatty acids are formed as a by-product. The reaction is comparable to what occurs in the digestive hydrolysis of fats in the alimentary tract. In the latter case the absorption of the products of digestive cleavage is followed by a resynthesis of fat, as is indicated by the appearance of neutral fats only in the thoracic duct lymph which carries the products from the alimentary epithelium to the general circulation. It has long been known that fatty acids can be absorbed and utilized, i. e., resynthesized into neutral glycerids or fats even when no glycerol is actually available in the digestive tract. The physiologist I. Munk³ clearly demonstrated this fact on man as early as 1890. Not long ago Lyman⁴ demonstrated, with animals, a utilization value of 82 per cent. for palmitic acid fed as such, in contrast with from 95 to 97 per cent. for the fat glyceryl palmitate and for lard fats. Lyman also demonstrated that after feeding free palmitic acid, glyceryl palmitate, or ethyl palmitate to white rats, essentially the same kind of fat is stored in the fat depots, and it consists largely of tripalmitin. Neither free palmitic acid nor ethyl palmitate in appreciable amounts is deposited unchanged in the fat depots.

In view of the foregoing facts the London Royal Society's experts seriously considered the possibility of applying to nutritive purposes the great stocks of fatty acids liberated from fats in the manufacture of explosives. According to their report it was estimated that some 100,000 tons a year of these fatty acids could be set free for the purpose, if they were found to be suitable. This would mean a substantial gain to the fat supply of the nation, which in prewar times was estimated at 1,651,000 tons, an amount far above the actual requirement; for fat more than any other food constituent was extensively wasted. Even if the products could not be used by man, so the experts argued, it was possible that they might be used by animals, and thus fat suitable for human food would be set free.

The new war-time human experiments, conducted at the University of Glasgow, at King's College and at the Cancer Hospital in London, by well-known physiologists,⁵ leave no doubt that fatty acids can be used as a source of fat in the diet of man. The fatty acids of hardened whale oil in amounts of 36 gm. per diem, or more than one third of the usual intake of fat, were

as thoroughly digested and absorbed as was the hardened oil from which they were prepared. Their administration for a period of six days caused no disturbance in the absorption of the other constituents of the food, as is indicated by the nitrogen and energy balances, nor any other disturbances in health.

In the more recent discussions of the value of fats in the dietary, some emphasis has generally been placed on the presence of a fat-soluble accessory factor or vitamin (fat-soluble A) in certain of the edible fats in contrast with other food fats, notably those from vegetable sources. It must not be assumed that fatty acids obtained as the result of drastic chemical processes can supply such factors. Fats or fatty acids may have a high calory value, be thoroughly digestible and highly palatable, without having the unique nutritive value that attaches to the vitamin-containing fats of milk and egg. Drummond⁵ looks on the extensive use of vitamin-free fats as a national menace. He writes:

One result of war conditions has been the disappearance, to a large extent, of the old prejudice against margarine. This, however, is a circumstance that is not free from danger to the community, especially as the present day margarines, though in some cases of satisfactory flavor, are mainly made of vegetable fats. It should in the future be compulsory that all margarines should contain a sufficient amount, either of real butter, of egg-yolk, or of oleo-oil (beef fat) in order that they may be more adequate sources of the fat-soluble accessory factor. Otherwise serious damage to the health of the population, particularly of young children, will be the inevitable result.

It must be remembered, however, that the fat-soluble vitamin has been demonstrated to occur in green leaves and certain animal tissues which enter into the human dietary.⁶ Without consideration of the diet as a whole, it may be premature to advise drastic procedures against otherwise wholesome fats merely because they cannot entirely replace milk or egg fats. In any event, however, the true composition of so-called butter substitutes ought to be clearly indicated and understood, so that responsibility for their use as nutrients may be founded on physiologic intelligence.

THE TREATMENT OF LEPROSY

For many ages, leprosy has been symbolic of the maximum of physical affliction, being regarded as the most abhorrent and hopeless of diseases. Even physicians have at times been guilty of a cruel and unscientific attitude toward the disease or, more particularly, toward the social problems that confront the leper as a result of the grotesquely distorted view of the disease held by the public at large, a view doubtless gained from biblical reading. Therefore, to record progress in the therapy of leprosy is especially gratifying. The progress has resulted from the convergence of two lines of clinical research, one wholly empiric, the other

resting on an immunologic basis. Both had in the past given some evidence of effectiveness in cases of leprosy.

Chaulmoogra oil (oleum gynocardiae, from the seeds of *Gynocardia odorata* and several varieties of *Hydnocarpus*), gurjun oil (gurjun balsam, from *Dipterocarpus laccis*) and cashew-nut oil (from *Anacardium occidentale*) have been used both internally and externally for a long time, chaulmoogra oil being in greatest favor. The internal use of the oils has been limited by the gastro-intestinal disturbances caused by the large doses required by such medication, if it is to be effective. To overcome this, a number of modifications have been suggested. Unna, for instance, used the sodium soap of gynocardic acid (isolated from chaulmoogra oil) in the form of a coated pill for internal medication. By combined internal and external medication, improvement in a number of cases was noted.

Later Deyke prepared a neutral fat obtained from a common streptothrix that had been isolated from a leproma. This substance was used for subcutaneous inoculation, and gave at times a considerable local as well as constitutional reaction. The effect on the leprosy nodules was, however, quite manifest, resembling in a measure the effect of tuberculin on the tubercle. Its use was, as a matter of fact, extended to the treatment of tuberculosis, and formed part of the method of immunization advocated by Deyke and Much.

Now we find that the subcutaneous method of medication has been applied to a sodium salt of gynocardic acid, the results of which treatment, as described by Muir¹ and Rogers,² are most encouraging. Muir has treated fifty cases by the subcutaneous and intravenous method, in most of which definite improvement was noted. In Rogers' series, thirteen out of fourteen patients made steady progress toward recovery, and in several cases apparently the disease was completely arrested and clinically cured. The use of sodium gynocardate A is interfered with by a rather severe local reaction on subcutaneous injection and injury to the veins on intravenous use, so that both Rogers and Muir have substituted a sodium salt of the fatty acids of cod liver oil, with seemingly equally good results, so far as the therapeutic effect can be judged in a relatively short period of time.

Just what mechanism is involved in the beneficial action that is said to follow the injection of these unsaturated fatty acids is not clear, although a number of suggestive possibilities present themselves. In both leprosy and tuberculosis we are dealing with infecting organisms that are rich in fats and lipoids (from 35 to 45 per cent. of the dried weight of the tubercle bacillus

consists of neutral fat, fatty acids, waxes and lipoids); both live in close adaptation to the tissues of the host, and the tissues react to them rather as they do to foreign bodies than to direct acute intoxication. These fat and lipid rich bacteria are probably susceptible to the action of fat-splitting enzymes of the body, and we must consider the possibility that the therapeutic injections may stimulate this lipolytic activity of the tissues.

Closely related is the effect on the lymphocytes, which contain lipase in considerable amount. The injection of fats and lipoids is said to be followed by a distinct lymphocytosis. Is the beneficial effect brought about by these cells as intermediaries? Or are we concerned with a more or less specific fat immunization proper, in the sense that Deyke suggested, or such as has been studied more recently by Warden? According to this conception, fats and fatty acids and lipoids in a variety of combinations are capable of acting in a specific antigenic capacity.

While the direct bactericidal action of the unsaturated fatty acids and their soaps cannot be excluded, nevertheless it seems more probable that their effect pertains rather of the nature of an "ergotropic," the term coined by von Groer to express the therapeutic effect of substances which, when injected in infectious diseases, act by altering the reactivity of the host rather than by acting directly on the invading parasite.

THE COLON AND SALINE CATHARSIS

The mode of action of purgative salts is not as well understood as it ought to be. Certain more recent discoveries of the action of substances used as laxatives have tended to confuse the situation still more. For example, magnesium sulphate (Epsom salt) exhibits a striking anesthetic effect when introduced into the circulation. Hence more than one physician has asked himself why such inhibition of the nervous functions and muscular relaxation do not manifest themselves in any of the multitudes of instances in which this chemical compound is ingested in order to empty the bowel. Again, if the laxative action of Epsom and Glauber's salt, of magnesium citrate and Rochelle salt, is a "salt effect," why is it missed when common salt—sodium chloride—is employed instead?

To these queries the investigation of the actual behavior of the different salts within the lumen of the bowel gives an intelligent answer. The saline laxatives represented by Epsom and Glauber's salts are not readily absorbed. The intestinal wall is not permeable to them, but behaves—to use the designation of the physical chemist—as a semipermeable membrane. Sodium chloride and water can readily traverse the intestinal epithelium in either direction; in fact, they invariably tend to do so in a way that will promote osmotic equilibrium on the two sides of the intestinal

wall. Sulphates fail to pass in the same manner; they accumulate in the bowel; water is retained therein or actually enters until the osmotic pressure practically equals that of the blood; and the distention of the intestine by the fluid volume is an immediate provocative of evacuation.

Most of this has long been well demonstrated though little appreciated. Recent studies by Goldschmidt and Dayton,¹ in the Hunterian Laboratory of Pathology at the Johns Hopkins University, have emphasized anew this characteristic behavior of the colon. Solutions of sodium chlorid introduced into the colon above or below the concentration level of this salt in the blood come into a chlorid partial pressure equilibrium with the blood. There is an attempt at total osmotic pressure equilibrium between the colon contents and the blood. The behavior of chlorids in traversing freely in either direction indicates that the colon is not characterized by a strictly one-sided permeability.

On the other hand, the colon behaves toward solutions of sodium sulphate essentially as does a semipermeable membrane. Magnesium sulphate shows even less absorption from the colon than sodium sulphate. From hypotonic solutions water is absorbed until the osmotic pressure increases to that of the blood. With hypertonic solution the volume increases through absorption of water until the same blood level is attained. In other words, "there is free passage of water with practically no diffusion of sulphate."

The Baltimore investigators point out that the failure of absorption of Epsom and Glauber's salts from the colon emphasizes the specific importance of the large intestine in saline catharsis. Hay,² to whom we owe classic researches in this field, supposed that sulphate was absorbed from the small intestine and then reexcreted into the large bowel, thereby explaining its undoubted accumulation in the colon. Goldschmidt and Dayton,¹ on the other hand, believe that the salt in the latter portion of the intestine is derived directly from the small intestine. Provided the cathartic salt reaches the colon in sufficient amount, they argue, so that by osmotic interchange between the blood and the colon contents enough fluid is introduced to increase the bulk and fluidity of the colon contents, catharsis will be assured. This might occur independent of the volume of fluid reaching the colon from the small intestine. The determining factor will be the amount of the salt which reaches the large intestine;

and since little is absorbed, this will be cumulative. Furthermore, once enough of an isotonic or hypertonic solution has reached the large intestine to increase the bulk and fluidity of the colon contents, catharsis is assured; for Goldschmidt and Dayton have shown that only a small quantity of the salt is absorbed in ten hours.

THE RELATION OF FORAGE POISONING TO BOTULISM

According to recent observations summarized by Dickson,¹ the variety of bacterial food poisoning known as botulism is not unusual in this country, being relatively common in the Pacific coast states. It has been found, further, that meat and meat products are by no means, as once believed, the exclusive, if even the main, source of the poison in question, which may occur also in canned vegetables and fruits, being produced by the growth of the anaerobic *B. botulinus*. The normal habitat of this bacillus is not known, and the exact manner in which vegetables and other food substances become contaminated is still a mystery. Botulism is not limited to human beings; it is a frequent cause of so-called limber-neck in the domestic fowl, and it may be responsible for certain forms of paralysis in various domestic animals. The toxic agent, which is a true toxin in the strict immunologic sense and consequently neutralizable by specific antitoxin, appears to have a rather wide range of action, and is peculiar in that it resists digestion and is absorbed from the digestive tract.

It has been suggested by Dickson that the occurrence of limber-neck in fowls eating refuse from the kitchen may prove of great diagnostic value in cases of suspected poisoning of human beings. The most recent development in connection with botulism is the demonstration that, in certain instances at least, outbreaks of so-called forage poisoning ("epidemic meningitis," "staggers," etc.) in horses and mules are in reality due to the toxins of *B. botulinus* or of very closely related bacilli. As long ago as 1901, Leonard Pearson pointed out the clinical analogy between forage poisoning in domestic animals and botulism in man, and more recently actual botulism seems to have been produced experimentally in horses and in donkeys.² Then Graham and his co-workers at the Kentucky Agricultural Experiment Station³ became interested in the question, and started investigations in forage poisoning that appear to be yielding results of great interest and value. In connection with a sporadic outbreak of forage poisoning from oat hay, these workers recovered a bacillus

like *B. botulinus* in growth, form and action in animals. Botulinus antitoxin—the serum of goats, sheep or cattle immunized with *B. botulinus* and its products—protected horses, mules and guinea-pigs against the forage bacillus and against sterile filtrates of both cultures of this bacillus which otherwise would produce symptoms that were indistinguishable from those produced by the typical botulinus bacillus. This work, consequently, goes far to establish definitely that anaerobic bacilli like *B. botulinus* may cause the condition known as forage poisoning. In another outbreak, this time in Illinois, Graham and Brueckner⁴ recovered a similar bacillus from the incriminated corn ensilage. In this case, they were able to demonstrate that antibotulinus serum agglutinated the ensilage bacillus and protected animals when injected with the bacillus in otherwise fatal doses, while the serum of animals immunized with the ensilage bacillus, in its turn, had agglutinative and protective effects with respect to the typical botulinus bacillus.

Close comparative studies of the different strains of these toxin-producing bacilli from different sources do not seem to have been made as yet; but the fact that they appear to be susceptible to the actions of the same immune serums indicates clearly a very close relationship if not complete identity. The symptoms of poisoning in horses and other animals strongly resemble those of botulism. After a variable incubation period the animals develop a general depression, progressive muscular weakness, incoordination, paresis of the pharyngeal and intestinal walls, impairment of vision, and ptalism. The only apparent real difference from the symptoms of botulism is that in man there is, as a rule, extreme dryness of the mouth, pharynx and nose; occasionally, however, the amount of saliva is increased, according to Dickson. Many questions are still unsolved; the mechanism of the production of the symptoms and how the toxin causes paralysis, impaired vision, etc., are as obscure as ever; the lesions, particularly in horses and other animals, have not been studied thoroughly; and the preventive and curative value of specific antitoxic serum in man and in animals remains to be determined. It is of special interest that in a desperate case of botulism described by McCaskey⁵ in his recent report of an outbreak at Decatur, Ind., recovery followed the injection of antibotulinus serum prepared by Graham,⁶ now of the University of Illinois. The free use of such serum in cases of botulism is a perfectly logical procedure warranted by the unequivocal results of experiments. For the present we must look to state and other experiment stations for antibotulinus serum, which is not yet an article of commerce. McCaskey urges that the serum should be

used early in suspicious food poisoning, as then "it should be entirely possible to prevent such tragedies" as the one he records. The hope arises that the demonstration of the relationship of forage poisoning to botulism may result in available supplies of potent antitoxin serum for man and beast.

NUTRITION AND SEX EXPRESSION

The world-wide campaigns for the control of venereal disease have brought the social relations of individuals and their sex expression into a peculiar prominence. Experience has shown the necessity of a changed attitude toward the problems of the sexual life. A few years ago no group of persons outside of the medical profession treated the subject in a frank manner; but today the champions of so-called social prophylaxis are ready to adopt a straightforward view in relation to the sexual instincts and to plan their campaigns for betterment with due consideration to physiologic and environmental factors as well as to purely moral or ethical tenets. A recent writer¹ has remarked that the physical, the mental and the moral being is the result of heredity, environment and education. Science, he adds, does not take cognizance of sentiment, for that is the product of culture, and they who permit themselves to be governed by a sentimentalism that ignores or conflicts with the established inexorable laws of nature must inevitably meet disaster.

A sane hygiene of sex must strive to learn what these "inexorable laws" of nature are. It is generally recognized that sexual emotions can be awakened or intensified by a variety of stimuli which affect the senses. The imagination undoubtedly plays a conspicuous part in many instances; nevertheless, aside from the more purely mental processes the sex expression finds its genesis in no small measure in the contributions of the special senses thereto. Sight and sound and touch enter into the peculiar complex in which physiologic and psychologic factors are mingled to give rise to the unique manifestations of sexual emotion.

Little is known and less has been taught regarding the purely physiologic background of these manifestations. It is understood, or at least assumed in a general way, that disease of the body as a whole may decrease or even abolish the sex expressions; thus, diabetes and extreme obesity are included among causes of sexual impotence. It has been very difficult, however, to secure definite information regarding possible relationships between the emotions of sex and special physical or metabolic functions of the organism. The topic is repulsive to those competent to furnish the facts; and even when they might be secured,

introspection and suggestion combine to make them of questionable value for a strictly scientific analysis. An exceptional instance for securing reliable information seems to have been afforded by the investigations of the Boston Nutrition Laboratory of the Carnegie Institution of Washington on the effect of a prolonged restricted diet on human vitality and efficiency.²

Editorial reference has already been made in THE JOURNAL to the outcome of these human experiments. Briefly, the basal metabolism of the students living at decidedly reduced weight level brought about by a diet representing from two thirds to one half of their supposed calorific requirement was about 18 per cent. lower per kilogram of body weight than prior to reduction. The systolic and diastolic blood pressures were lowered to about 90 and 65 mm., respectively. The pulse rate showed a marked drop. For example, five of the subjects showed many pulse rates 35 beats or below, and one man gave seven counts at 29 beats per minute. Body temperature, measured rectally, was normal, but the men complained of feeling the cold and wore more clothing. Neuromuscular coordinations presented some decrement; not enough, however, to interfere seriously with the duties of everyday life. There was no falling off in the quality or amount of the scholastic work. Strength tests indicated some decrease, but the normal amount of common physical activity appears to have been maintained. The men were not apparently lacking in vitality, nor were they inefficient. When engaged in vigorous athletics with their fellows, a stranger could not have picked them out.

Information cautiously acquired from the twenty-four young men who may be assumed, because of their training at the International Y. M. C. A. College at Springfield, Mass., to have a sound and wholesome attitude regarding these matters, reveals the circumstance that associated with the physical condition resulting from the low diet there was a diminution in sex activity.³ It is needless to reiterate here the correlated opinions on which this conclusion was based. Miles³ has called attention to the fact that, in these undernourished students, decreased sex expression accompanied a diminished rate of basal metabolism; and he ventures to remind us that the sex instinct is commonly stronger in men than in women, who have a lower basal level of metabolism. It is not on this ground illogical, Miles writes, that a lowered metabolism in men might reduce the manifestations of the sex instinct. Nature may require a high metabolic level for purposes of race propagation.

² Benedict, Miles, Roth and Smith: Human Vitality and Efficiency Under Prolonged Restricted Diet. Pub. 280, Carnegie Institution of Washington, 1918; Benedict, Miles, Roth and Smith: The Effects of a Prolonged Reduced Diet on Twenty-Five College Men, *Proc. Nat. Acad. Sci.* 4: 149, 1918.

³ Miles, W. R.: The Sex Expression of Men Living on a Lowered Nutritional Level, *J. Nerv. & Ment. Dis.* 49: 208 (March) 1919.

¹ M. Ichlow, C. W. The Sexual Life, St. Louis, C. V. Mosby Company, 1917.

Miles' conclusion from his most unusual study has a direct interest for medical practice:

Any dietetic régime which, even though it affects the external appearance and performance of an individual but little, definitely lessens the expression of the sex instinct, causing one sex to take but little interest in the other, would seem to be disadvantageous to the species if indefinitely prolonged and if the instinct made no adjustment thereto. Any general conclusions regarding a lowered nutritional level produced by prolonged reduction in diet may not disregard the effect on the sex instinct or its manifestations. On the other hand, the results clearly indicate a method of treatment for achieving restraint of sexual tendencies in pathologic cases of sexual dissipation.

Current Comment

THE UTILIZATION OF MILK FAT BY INFANTS

The study of the feces is fundamental to the interpretation of the results of infant feeding. Mere inspection of the stools, without a first hand appreciation of the chemical significance of the pictures which they present, has often led to erroneous deductions. Only a few years ago, curdy masses in the feces of the young might have been reported as mucus, casein flocks, or residues of soap, according to the conjecture of the untrained observer. The advent of physiologic chemistry as a part of the clinical routine has helped to establish more rigorous criteria. Haphazard guesses are no longer justified when facilities for chemical control are available. The new point of view—the demand for exact information as to the make-up of the feces—has helped to secure new data of interest in the physiology of digestion during infancy. Not long ago we reported the experience of Holt, Courtney and Fales¹ at the Babies Hospital, New York, who found that the stools of breast-fed infants receiving an average intake of 28 gm. (1 ounce) of fat daily contained not more than 1.1 gm. of this amount. This retention of fat to the extent of 95 per cent. corresponds very favorably with a "coefficient of digestibility" of from 90 to 95 per cent. for fat used in the mixed diet of an adult man. In the infants, the excreted fatty material comprises about half of the dry matter of the entire feces, and consists largely of soaps. Quite similar results have since been recorded for infants fed on modifications of cow's milk.² The average proportion of the fat of the diet retained with normal stools was 91 per cent. of the intake. The retention was little lower when the stools were somewhat harder or softer than normal, or were not homogeneous, or contained more or less mucus without being distinctly watery. As the water in the stools

increased, the degree of fat retention decreased markedly, reaching in severe diarrhea 58 per cent. of the intake. Hence the digestion by infants of cow's milk and its modifications need not be essentially poorer than is the utilization of the same ingredients of breast milk. The nutritive comparisons belong, perhaps, on a qualitative rather than a quantitative basis.

THE HOSPITAL INTERNSHIP

For many years the importance of a hospital internship as an essential part of a physician's training has been recognized. During the last twenty-five years medical graduates, in steadily increasing numbers, have voluntarily secured such training. At the present time the percentage of graduates so trained is 90 per cent. That a larger proportion did not secure such internships in the past was due, on the one hand, to the unusually large number of graduates turned out from the medical schools, and, on the other hand, to the limited number of hospitals that were willing to make use of interns. This condition has been corrected in both directions. Through the higher preliminary qualifications required for admission to medical schools, the unusually large number of graduates was reduced to more normal numbers, and the improved qualifications possessed by these graduates induced a larger number of hospitals to utilize their services as interns. The time has arrived when all medical colleges should require the internship as an essential for graduation. Eight medical schools have already taken such action,³ and four of these have enforced the requirement with respect to graduating classes. The method of procedure was described in an article by Dr. John M. Dodson² published last week. Although the general adoption of the requirement will be hastened by the action of state licensing boards³ in requiring an internship as an essential for the license, it is the medical school that is in the best position to insure that the intern training shall be of high quality. The intern training, as an important part of the physician's instruction, comes within the function of the medical school. The medical school best knows the clinical needs of the students and can best supervise this training in a group of selected hospitals. Since there are now more than enough hospitals to provide internships for all graduates, and since nearly all graduates are voluntarily securing such internships, it will not be a hardship to require it as an essential for both the M.D. degree and for the license to practice. On the contrary, it will result in improving the quality of the intern's training; it will stimulate an interest in modern methods on the part of the attending staff; it will improve the records and routine methods employed in the hospitals; and, finally, it will result in far better care and treatment of the patients.

3. Nine State Boards, listed in *THE JOURNAL*, Aug. 16, 1919, p. 521, are now requiring a year of intern training as an essential for the license.

GENEALOGY AND POPULATION

The testing of old and familiar hypotheses and general impressions by scientific methods is frequently possible by the application of statistics. A recent genealogical study of population¹ presents some results of general interest. Five genealogies were used, extending over a period of 250 years and furnishing more than 20,000 individuals. Distinct correlation between longevity and fertility in both mothers and fathers is shown; in addition, of course, to the fact of a longer period of reproductive capacity. There is also clear evidence of correlation between age at marriage and fertility, the lowest ages at marriage being associated with the greatest fertilities. Tabular presentation of the fecundity of first-born children showed no appreciable variation from that of the total stock. The data for twinning are strikingly definite, for out of eighty-seven cases of twinning, fifty-six occurred at the end of the mother's reproductive period, and of the five genealogies of approximately equal size, two provided fifty-seven of the occurrences of twins. In connection with the general population question it is noted that the average number of children per married couple was 5.8 for the period 1651-1700; rose to 6.1 for the last fifty years of the eighteenth century, and fell to 3.0 for 1851-1900. Corresponding to this change was a lengthening of the average interval between births from about 2.5 years in the first two periods to 3.41 years in the last.

PHYSICIANS AS UNPAID COLLECTION AGENTS

Physicians in different parts of the country have received letters addressed, not to them personally, but to them as "Town Physician" of the city or village in which they live. These letters, typewritten and obviously "form letters," read:

Dear Sir:—Recently I wrote JOHN DOE of your city but my letter was returned to me by the postoffice undelivered which leads me to believe that the family has moved to some other address without letting me know. If it is not asking too much of you, I assure you it would be a great favor if you could advise or find out for me without putting yourself to too much trouble where a letter can reach this party. It is a matter of considerable importance.

Thanking you for your kindness and assuring you of my appreciation, I remain Yours very truly, HELEN TAYLOR.

The name of the person inquired about, of course, varied; so, may it be said, did the name of the person from whom the letter purported to come. Instead of being a letter from "Helen Taylor" it might be from "W. J. Mitchell" or from some other party, although the handwriting of the signatures was suspiciously similar. In every case a stamped envelope directed, as the case might be, to "Helen Taylor," "W. J. Mitchell," etc., accompanied the request for information. In every instance, too, this envelope was addressed to 146 W. 40th St., Chicago. The JOURNAL'S investigators found that there is no 146 W. 40th St., and, in fact, could not be, as this address would come at a place that is occupied by railroad tracks. It became obvious, therefore, that these various form letters, evidently

from a common source but sent out under different names, were being delivered through the connivance of a postoffice employee. THE JOURNAL laid the matter before the chief inspector of the Postoffice Department at Washington with a request for information. In due time the inspector reported that:

It was ascertained that the communications in question were form letters sent out by the Hartman Co. of Chicago, Ill., with a view to locating persons who owed them accounts.

The concern referred to in the Inspector's report is the Hartman Furniture and Carpet Company, which sells house furnishings on the instalment plan. Its advertising slogan is "Let Hartman Feather Your Nest." So long as physicians remain good-natured and "easy," the Hartman concern is presumably not going to let a chance to feather its own nest go by. Why pay a collection agent when "Town Physicians" are so accommodating? We might add that the most recent letter of this sort that we have seen was addressed to "Minister of Gospel or Town Physician." Religious papers please copy!

WAR RISK INSURANCE

It is reported that more than 50 per cent. of the soldiers and sailors carrying war risk insurance have discontinued their payments; that—almost unbelievable as it may seem—the War Risk Insurance Bureau has not even the addresses of 50 per cent. of its former clients. If this is true it is greatly to be regretted, since the government insurance policies offer to the insured many advantages not available through private insuring companies. In accordance with the terms of the law, the war policies are now being converted to peace-time rates. The latter are considerably less than rates for similar policies given by private companies. The convenience of payment, safety of investment, and other factors tend to make this insurance superior to any private insurance that may be carried. Furthermore, the government is anxious to meet the views and wishes of the insured in every way; for example, some of the insured objected to the method of payment of policies by monthly payments. In an endeavor to satisfy all the insured, a commission has recently been appointed, under the chairmanship of Charles E. Hughes, to make a survey of the situation with a view to making the government insurance even more satisfactory than it now is. A recent decision of the Secretary of the Treasury is to the effect that discharged soldiers, sailors and marines who have dropped or canceled their insurance may reinstate it within eighteen months after discharge, without paying the back premiums. They will be asked to pay only the premiums for two months on the amount of insurance desired. The only stipulation is that the former service man be in as good health as at the date of his discharge. A special form (No. 742) has been prepared by the Bureau of War Risk Insurance to permit application for reinstatement. It can hardly be conceived that any medical officer entitled to this insurance should fail to avail himself of its full benefit. It has been repeatedly asserted that the physician is a poor business man and an easy prey for the canny purveyor of fake investments. It is to be hoped that there are

¹ L. Jones, C. E.: A Genealogical Study of Population, Publications American Statistical Association, 14: 201 (Dec.) 1918.

but few physicians included among those who have failed to take advantage of what the government has offered them through its insurance department. If they have, the new decision on reinstatement gives them time for thought and an opportunity to restore themselves to their original enviable status.

ADROITNESS IS CORRECT

Gentlemen who are engaged in the chiropractic trade—we use the word "trade" advisedly—are furnished Helpful Hints for Ambitious Advertisers by an Indianapolis concern that makes a specialty of this line. In one of the numerous leaflets sent out from this source to "Chiropractors" they are urged to "employ an advertising man" and not attempt to write their own copy. It is pointed out that there are in many states laws prohibiting fraudulent advertising, and "today the liar in print is soon run to earth." While we are unable, regretfully, to agree with the last statement, the conclusions drawn from this premise are more easily accepted:

"... to advertise inside the chiropractic, medical and truth laws, requires some adroitness, some ingenuity of expression, some more than common ability as a wordsmith."

We'll say it does!

Medical Mobilization and the War

Personnel of the Medical Department

For the week ending August 15, there were 8,895 officers in the Medical Corps, a decrease of 766 from the previous week. The Medical Reserve Corps contained 3,231. The total number of physicians discharged since the beginning of the war is 23,463.

Naval Officers Promoted to Rank of Commander

The Navy Department announces the promotion of the following reserve officers to rank of commander:

Robert G. LeComte, Philadelphia; William B. Brinsmade, Brooklyn; Stanley Stillman, San Francisco; Eugene F. DuBois, New York; Rex Smith, Los Angeles; John C. DeCosta, Philadelphia; Milton J. Roseman, Boston; George G. Ross, Philadelphia; Alphon W. Hewlett, San Francisco; Hobart A. Hise, Philadelphia; Robert B. Greenough, Boston; Judson Dohand, Philadelphia; James F. Talley, Philadelphia; Edward M. Foote, New York; Paul A. Lewis, Philadelphia; Guy Cochran, Los Angeles; Verne A. Dodd, Columbus, Ohio; Edgerton L. Crispin, Los Angeles; John A. McGinn, Philadelphia; L. Roy G. Crandon, Boston; Harold D. Meeker, New York; Nelson H. Clark, Pittsburgh; Halsey DeWolf, Providence; Charles W. Moots, Toledo, Ohio; George A. Matteson, Providence; James T. Hannan, Brooklyn; Francis J. Dever, Philadelphia; Frank C. Gregg, Manor, Texas; Clifford E. Henry, Minneapolis; Porter B. Brooks, Toledo, Ohio; Clinton C. Tyrrell, Minneapolis; Frederick O. Williams, Columbus, Ohio; Harvey M. Righter, Philadelphia; Zachary T. Scott, Austin, Texas; William C. Newton, Revere, Mass., and William H. Arson, Upper Montclair, N. J.

Awards of Distinguished Service Cross

The distinguished service cross was awarded by the commanding general, American Expeditionary Forces, for extraordinary heroism in action in Europe to the following named officers of the American Expeditionary Forces and of the Allied armies:

RAY H. HUMPHREY, Major, Medical Corps, Union, N. Y., 130th Inf. For extraordinary heroism in action near Bois de Septarges, France, Oct. 4, 1918. Having just been transferred to the 130th Inf., Major Humphreys (then captain) was seriously wounded in the head while on his way to take up his work at the regimental aid post. He nevertheless refused to be evacuated, but continued on duty caring for the wounded at this place. He later proceeded under severe artillery fire to the battalion aid post, where he continued his work under most trying conditions.

ERNEST W. SLUSHER, Major, Medical Corps, Kansas City, Mo., 140th Inf. For extraordinary heroism in action near Charpeny,

France, September 29-30, 1918. Although severely gassed, he continued on duty until he collapsed twice, and was carried each time to a dressing station. Advised to go to a field hospital for treatment, he waited until he had partially recovered and then returned to duty in the field, working continually among the wounded and exposing himself to hostile fire.

ALBERT W. LINDBERG, Captain, Medical Corps, Wellboro, Ill., 2d Machine Gun Battalion. For extraordinary heroism in action near Exermont, France, October 8, 1918. Crawling out over shell torn ground and in face of direct machine gun fire, he rescued a soldier whose leg had been shattered by shell fire. By performing an amputation while constantly exposed to sniping and machine gun fire, he made it possible to evacuate the soldier to safety a few hours later, when the infantry moved forward.

SAMUEL J. MARKS, 1st Lieut., Medical Corps, Philadelphia, 14th Inf. For extraordinary heroism in action near Malancourt, France, Sept. 27-29, 1918. Lieut. Marks advanced with the foremost elements of his battalion, dressing and evacuating the wounded under machine gun fire for a period of 12 hours. On September 29, when his and station was shelled, several patients and attendants being killed and wounded, remained at his post caring for patients who had received fresh wounds and assisted in their evacuation.

CHAUNCEY E. DOWELL, 1st lieutenant, Medical Corps, 271st Infantry. For extraordinary heroism in action near Russ Farm, Ardeuil, Montfauvelles, and Freres Farm, France, Sept. 28-30, 1918. Throughout three days of most intense action Lieut. Dowell worked unceasingly in caring for the wounded, disregarding a severe wound which he himself received in the neck by a shell fragment. He remained continuously on duty giving an example of fortitude and courage to all about him.

Distinguished Service Medal Awarded

Major J. R. CUKKIN, Medical Corps, United States Army, for exceptionally meritorious and conspicuous service when in charge of Camp Hospital No. 1, at Camp Upton, N. Y., during the serious epidemic of influenza at this camp in September and October, 1918. Due to his great energy and good will, and unswerving to meet death in any form, remarkable results were obtained at this hospital.

Croix de Guerre Awarded

WILLIAM H. HOLMES, Major, M. C., U. S. Army, Chicago, has been awarded the Croix de Guerre.

Citations for Bravery

The following officers have been cited for bravery: HERBARD K. HINDE, Capt., M. C., U. S. Army, San Angelo, Texas, "for exceptional meritorious and conspicuous service while under shell fire on the Meuse-Argonne front, Oct. 20, 1918."

RALPH H. McFADDEN, Lieut., M. C., U. S. Army, Chester, S. C., has been awarded certificate of authorization to wear the arms of the city of Langres, France.

ARTHUR A. LAW, Lieut. Col., M. C., U. S. Army, Minneapolis, was cited by General Pershing, "for exceptional meritorious and conspicuous service" at Base Hospital No. 20, France.

Given British Military Cross

JOHN M. HAYES, Capt., M. C., U. S. Army, Decatur, Ill., has been awarded the British Military Cross for valor in maintaining an advanced dressing station under fire at the Amiens front.

Receive Legion of Honor Decorations

ALEXANDER BRUNO, Capt., American Red Cross, New York City, has been awarded the cross of the Legion of Honor, by the French government.

DR. WILLIAM PALMER LE CAS, San Francisco, who has been in charge of the rehabilitation work among French refugee children, has been made a Chevalier of the Legion of Honor and has also been given the Médaille d'Epidémie.

GUSTAVUS M. BLOCH, Lieut.-Col., M. C., U. S. Army, Chicago, commander of U. S. Base Hospital No. 208, has been awarded the Legion of Honor by the French government.

DR. WILLIAM J. FRENCH, Washington, D. C., who went to France in 1918, and opened numerous nursing clinics in the densely settled districts of Paris, has been given the Cross of the Legion of Honor.

Citations with Palm

DR. MARY L. EVANS, Portland, Ore., who has been on duty with the French army for ten months as specialist in nervous and mental diseases, has received the citation with palm and the Médaille de Reconnaissance from the French government.

HONORABLE DISCHARGES, MEDICAL
CORPS, U. S. ARMY

NOTE.—In the following list, L. signifies lieutenant; C., captain; M., major; L. C., lieutenant-colonel; Col., colonel.

United States Maximum Opium Consumer.—As the result of investigations made by a committee appointed by the secretary of the treasury, March 25, 1918, to investigate the traffic on narcotic drugs, it has been determined that from ten to sixty times as much opium per capita is consumed annually in the United States as in any other country from which reliable records can be obtained. The investigations included simply the traffic in opium and coca leaves, their preparations, and habit-forming alkaloids. The following table shows the per capita consumption of opium by the United States and certain foreign countries:

Country	Population	Total Annual Consumption, Pounds	Consumption per Capita, Grams
Austria	46,000,000	3,000 4,000	12 to 35
Italy	33,000,000	17,000	2
Germany	60,000,000	17,000	2
France	40,000,000	17,000	3
Portugal	5,700,000	2,000	212
Holland	6,000,000	3,000	312
United States	92,000,000	470,000	36

* The population is that given for 1910.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

CALIFORNIA

Unlicensed Practitioners Arrested.—A. E. Mohr, Pasadena, and G. G. Sanchez and Donald Donovan of Los Angeles were arrested by an inspector of the State Board of Medical Examiners on the charge of practicing medicine without a license.

"Cancer-Cure Expert" Arrested.—M. M. Winchell of Los Angeles has been arrested on the charge of responsibility for the death of Mrs. Nettie Daniels who, it is alleged, died a few minutes after Winchell had injected a solution of his "cancer-cure" into her arm. Winchell was released on bail of \$5,000.

Woman Physician Charged with Murder.—Dr. R. May Minaker, San Francisco, was rearrested and charged with murder on account of the death of Mrs. Jadriga Jazwicz, victim of an illegal operation. She was released on \$10,000 bail. Several weeks ago Dr. Minaker was in the police court on the same charge but after a hearing was dismissed.

Card Sentenced to San Quentin.—Dr. William S. Card, San Francisco, recently convicted of second degree murder as a result of the death of a young woman on whom he had performed a criminal operation, was taken to San Quentin to begin the service of a sentence of from ten years to life. He has been arrested forty-two times but almost invariably managed to escape punishment.

Physician Indicted on Seventeen Fraud Charges.—Dr. George F. Brackett, San Francisco, former federal and county physician at the county jail, San Francisco, has been arrested on the charge of defrauding the government out of thousands of dollars while employed to care for prisoners at the county jail. The indictment contained seventeen charges of fraud. Dr. Brackett was released on bail of \$5,000.

Personal.—Dr. Etta G. Gray, Los Angeles, president of the war work committee of the National Women's Association, sailed for Europe, August 4, for a year of service in France and Serbia. Her first work will be the establishment of a chain of hospitals in Serbia.—Dr. John Mark Lacey, Los Angeles, medical director of the Los Angeles County Hospital, has resigned.—Dr. Herbert R. Stolz, medical adviser to the male students of Stanford University, has resigned.—A dinner was given by the public health department of Oakland and the public health center of Alameda County at Oakland, August 7, in honor of Drs. William Thompson Sedgwick, Boston, and Richard A. Bolt, Cleveland. The topic for discussion was the prevention of disease.

ILLINOIS

Personal. Health Commissioner John D. Robertson, Chicago, was reelected chairman of the city morals commission, August 11.—Dr. Charles A. Johnson, Barry, has been commissioned captain, M. C., III, N. G., and assigned to the depot organization of the Eighth Infantry.

Scale for Telephone Advice Raised. The secretary of the Kane County Medical Society announces that in the medical news for August 16 the item which stated that Kane County physicians will charge 50 cents for telephone information hereafter is incorrect. The fee for such advice is to be \$1.

Sanatorium Opened. The McLean County Tuberculosis Sanatorium at Bloomington was dedicated with impressive ceremonies, August 17. The principal address was delivered by Dr. George F. Palmer, Springfield, president of the Illinois Tuberculosis Association. The sanatorium has been erected at a cost of \$50,000, and will accommodate 250 patients.

Violators of Drug Law.—Dr. Thomas Roberts, said to have been at one time a well known physician of Chicago, was arrested, August 16, by federal agents, charged with violation of the Harrison Narcotic Law, and held in bonds of \$2,000. He is accused of having given narcotic prescriptions to drug addicts and of having himself made sales of habit-forming drugs.

New Officers. The Medical Women's Club, at its August meeting, elected the following officers: president, Dr. Grace

H. Campbell; vice presidents, Drs. Cecelia P. Kimball and M. Osborne Lichner; secretary, Dr. Adelaide M. Tyrrell, and treasurer, Dr. Emma H. Salisbury Peterson, all of Chicago.—Arthur E. Gammage, Capt., M. C., U. S. Army, Chicago, has returned from overseas, and has accepted an appointment as acting chief of the bureau of hospitals, under the department of health.

Licenses of Four Physicians Revoked.—The Illinois State Department of Registration and Education has revoked the following physicians' licenses for the reasons given: Dr. Henry G. Meyer of Chicago for unprofessional and dishonorable conduct; Meyer at present is serving a sentence in the Cook County jail on the charge of pandering. Dr. Joseph M. Moses for seeking to obtain money and practice in his profession under false pretenses; he was arrested for this in the spring of 1917 and was sentenced to eighteen months in the penitentiary, and carried his case on appeal to the supreme court which, in June, 1919, sustained the action of the lower court; Dr. Moses is confined in the Joliet Penitentiary. He is said to have represented himself as an officer of the state board of health in connection with the case for which he was punished. Dr. John D. Young of Brookport, Ill., on the ground that he "is a person addicted to the use of morphin, opium, cocaine or other drugs having a similar effect." Dr. Arthur L. Blunt of Chicago for unprofessional and dishonorable conduct in violation of the United States laws governing the use and dispensing of narcotic drugs. A previous action of the department revoking his license had been set aside by the court after the case had been carried to the supreme court of the state. Dr. Blunt at present is a prisoner in the federal penitentiary at Fort Leavenworth, Kan.

INDIANA

Held Under Charges.—Dr. Joseph H. B. Adams, Indianapolis, is reported to have been arrested, August 2, charged with having performed an illegal operation which caused the death of Mrs. Edna Bartrand. Dr. Adams was released under bonds of \$1,000.

Tuberculosis Activities.—Dr. Marion A. McDowell, Peru, was elected president of the Miami Tuberculosis Society at the meeting, held August 3.—Irene Byron County Tuberculosis Hospital, near Fort Wayne, was dedicated with impressive ceremonies, August 10. The principal address was delivered by Dr. John N. Hurty, Indianapolis, secretary of the state board of health.

Overcharges by Druggists.—Dr. Hugo O. Pantzer, chairman of the committee formed by the Indianapolis Medical Society to investigate alleged exorbitant charges for prescriptions by Indianapolis druggists, reported that the committee had found cases of extraordinary prices, but that this was not general, and that the high prices now being charged are justified in many instances.

Personal.—Dr. Sterling P. Hoffmann, Decatur, has been appointed medical director of the Lincoln Life Insurance Company, Fort Wayne.—Dr. Horace C. Martindale, Pendleton, is under treatment in a hospital in Indianapolis.—Dr. Frank E. Wolfe, New Albany, has been appointed medical examiner of the Modern Woodmen of America, for Indiana, succeeding his father, Dr. Zelotus C. Wolfe, Corydon.—Dr. Lewis N. Geisinger, Auburn, has been reappointed surgeon of the Michigan division of the P. C. C. and St. L. Railroad.—Dr. Cyrus W. Campbell, Hammond, is convalescent after a surgical operation.

MARYLAND

Physicians and Druggists in Raid.—In a raid made in Baltimore, August 9, in an effort to stamp out the illegal traffic in narcotic drugs, United States internal revenue officials and deputy marshals arrested seven physicians and three pharmacists.

Sanatorium Loses Site.—The opposition by the residents of Towson and vicinity to the proposed hospital for tuberculous negroes has been successful and it has been definitely stated that the hospital will not be located in that town. The option on the property held by the state, which adjoins the Endowment Sanatorium, has lapsed and as yet no plans have been made to secure a new site.

Drug Clinic Urged.—Nothing but the inadequacy of the law stands in the way of solving the drug evil in Baltimore, according to the health officials, who are daily advocating a municipal clinic, with laws empowering magistrates to commit addicts to the ward. Medical men, including hos-

pital superintendents and specialists, and private practitioners have been clamoring for such an institution for months. United States authorities, especially those in charge of the prosecution of the violations of the Harrison Act, are unanimous in the belief that a city clinic would eventually end their troubles with drug cases. Addicts themselves want the hospital more than all the officials combined, for they want to be cured and realize that real cure lies only in a municipal institution. The drug evil in Baltimore has been brought to the attention of the public forcibly lately by the raids of the Federal authorities and by suicides because of the shutting down of the supply.

Personal.—Harry S. Purnell, Lieut.-Col., M. C., U. S. Army, former commandant at U. S. Army General Hospital No. 2, Fort McHenry, who established U. S. Army General Hospital No. 2 in August, 1917, and was in command until July, 1919, when he was succeeded by Col. Henry Page, has been ordered to Camp Custer, Battle Creek, Mich., where he will assume the duties of camp surgeon.—Dr. William S. Archer, Bel Air, sustained severe bruises and two fractured ribs when the buggy in which he was riding collided with an automobile bus near Bel Air, recently.—Dr. Henry O. Reik, Baltimore, has been secured as executive secretary of the New York Association for Medical Education and will devote his entire time to the development of the project.—Dr. Emil Goetsch, Baltimore, associate professor of surgery in Johns Hopkins University and surgeon to Johns Hopkins Hospital, has been appointed professor of surgery and visiting surgeon to the Long Island College Hospital, Brooklyn, director of the surgical service and head of the department of surgery throughout the college, hospital and dispensary.—Cranford H. Douthirt, associate professor of bacteriology at the University of Maryland, has been discharged from the army after two years' service at Fort Bayard, New Mexico.—Dr. Charles B. Ensor, who served as major in the medical corps in France, recently returned home.—Dr. Edward A. Luper, who recently returned after a year's service with the American Expeditionary Forces, has resumed his duties at the University Hospital.

NEW JERSEY

Personal.—Dr. John S. Conroy, Burlington, who went overseas with the 114th Ambulance Corps, was promoted to the rank of captain.—Thomas L. Rhoads, Col., M. C., U. S. Army, recently division surgeon of the Eightieth Division and head of the department of sanitation and civil affairs at the advance headquarters of the army of occupation, has taken over the duties of camp surgeon at camp Dix.—Mr. Frederick L. Hoffman, third vice president and statistician of the Prudential Insurance Company, Newark, sailed, August 2, for England, for the purpose of making an intensive investigation into the effects of war on insurance, including the methods and results of national health insurance in Great Britain. He expects to attend the annual meeting of the Eugenic Educational Society at Cambridge, and the meeting of the British Association for the Advancement of Science at Bournemouth, will represent the Eugenics Research Association in the interest of the forthcoming eugenic congress, will also, on behalf of the National Safety Council, visit the London Safety Council. He expects to return early in December.

NEW YORK

Sued for Typhoid Outbreak.—Seven suits for damages, aggregating \$125,000, have been brought against Francis P. Garvan and his wife, Mrs. Mabel Garvan of New York, by residents of Saranac Lake, Tupper Lake, Malone and Plattsburg, because of an epidemic of typhoid fever among the men employed in the construction of Kamp Kill Kare on Nacquette Lake early in the summer of 1916. The men became ill between April 1, 1916, and July 5 of the same year. There were 129 men employed when the epidemic started and a number of them died.

New Hospital Buildings.—Contracts totaling \$3,302,750 for new construction at state institutions for the insane and feeble-minded are being let by the state this summer. Of this \$1,100,000 will be spent at the Utica State (Marcy Division); \$420,000, at the Middletown State Homeopathic Hospital; \$478,330, at the Central Islip State Hospital; \$350,000, at the Kings Park State Hospital; \$175,000, at the Brooklyn State Hospital; \$67,000, at the Hudson River State Hospital; \$647,000, at Letchworth Village, and \$65,420, at the Newark State School for Mental Defectives.

New York City

Narcotic Society Officer Held.—Christian F. J. Lasse, secretary of the American Medical Society for the Study of Alcohol and Other Narcotic Drugs, is reported to have been arraigned before State Commissioner Hitchcock, August 9, and held under \$5,000 bail, charged with trafficking in habit-forming drugs.

Personal.—Dr. S. Josephine Baker, director of the bureau of child hygiene, has been appointed a member of the advisory committee for the Federal Children's Bureau, Washington, D. C., and a special agent for the children's bureau in New York City.—Dr. Alphonse Raymond Dochez of the Rockefeller Institute for Medical Research has been appointed associate professor of medicine at the Johns Hopkins University.

Drug Addiction Made Reportable.—At a meeting of the board of health, held July 22, 1919, the following resolution was adopted: "Resolved that Section 1 of the Sanitary Code be and the same is hereby amended by adding thereto, a new subdivision, to be known as Subdivision 47, to read as follows: 'Pestilential Disease: Shall be deemed to include the conditions and symptoms resulting from the habitual use of habit-forming drugs, and known as drug addiction.'"

New Building for Health Department.—The erection of a new building for the health department has been made possible by an appropriation of \$1,000,000 granted by the board of estimate. The new building will be brick, twelve stories high, and will occupy almost the entire area of the plot, 100 by 100 feet, in West Thirtieth Street between Seventh and Eighth Avenues, now occupied by the old Thirtieth Street Police Station. This building will permit the centralization of the health department under one roof and will make possible a closer coordination of effort and increased efficiency. Three or four floors of the new building will be given over to the work of the bureau of laboratories which is now scattered among a number of institutions. The building will have a large auditorium, and one floor will be devoted to a medical library.

Imported Smallpox Discovered.—A man having smallpox recently presented himself at one of the venereal clinics of the health department. He was found to be a member of the crew of a fishing vessel that recently discharged a cargo at Promised Land, L. I., and subsequently came into New York Harbor. Investigation revealed that another member of the crew was ill in Jersey City, and his case had been diagnosed as chickenpox. Two other members were ill at Promised Land. A committee appointed to investigate the situation found all these men suffering from smallpox. Since then eight additional cases have developed among the crews of this and a sister vessel. The United States Public Health Service has been advised of these facts with a view to having action taken that will bring to light the true situation in Nova Scotia from whence the vessels came and where it is reported smallpox is prevalent.

The Health Department and the High Cost of Living Crisis.—Health Commissioner Royal S. Copeland has issued a warning statement that the board of health would revoke the permit of any dealer in dry eggs, liquid eggs, or frozen eggs, or the proprietor of any slaughter house, caught hoarding food or profiteering. The board of health issues permits for such business and hence can revoke licenses "provided it does not act unfairly, tyrannically, unreasonably, or on false information and without reasonable ground for apprehending that the public safety, health, or welfare may be in danger." Governor Smith has expressed the opinion that the board of health should be placed in charge of all measures regulating the sale of foods and other necessities of life in this city. He states that "surely an insufficiency of food from whatever cause is a matter of public health" and is of the opinion that "through the board of health we may come to a solution of the problem."

Department Takes Sea View Hospital.—The health department has taken formal possession of the Sea View Hospital as a home for the treatment of drug addicts. Commissioner Royal S. Copeland estimates that there are about 2,000 addicts in urgent need of care and treatment and in order to provide such treatment he believes the use of the institution will be required until the first of the year. The tuberculous patients at the institution are being classified and transferred to other institutions. The taking over of the Sea View Hospital for the use of drug addicts does not meet with the approval of the committee on tuberculosis of which Dr.

James Alexander Miller is chairman. The committee has adopted resolutions protesting against the opening of this institution to drug addicts and copies have been sent to the mayor, Health Commissioner Copeland, Charities Commissioner Coler and members of the board of estimate. The communication expresses sympathy with Dr. Copeland's work in caring for drug addicts, but bases its protest on the ground that this use of the Staten Island hospital will deprive tuberculous patients of the superior advantages of Sea View. The Staten Island Civic League is taking drastic measures to prevent the treatment of addicts in the Staten Island institution.

OHIO

Smallpox at Youngstown.—The number of smallpox cases for Youngstown shows a decrease, as only eighteen were under quarantine, August 6, and as no new cases have been reported since July 21.

New Quarters for State Board.—The state department of health has leased the entire top floor of the Clinton Building, Columbus, and will transfer to its new locations all its offices, excepting the laboratory, which will remain on the university campus.

Selection of District Boards.—Meetings are being held throughout the state for the organization of local health administrative agencies. At the preliminary meetings the mayors of cities and chairmen will organize themselves into a district advisory council, and elect a board of health of five members, two of these members must be physicians, one a farmer and one an attorney.

Scientific Sessions of State Society.—The Ohio State Medical Association is holding a series of meetings throughout August and September. Meetings have already been held at Chillicothe, Bucyrus, Cedar Point, Bellefontaine, and Portsmouth, and will be held at Canton, August 20; Zanesville, August 27; Athens, September 2; Marysville, September 4; Marion, September 11; Dayton, September 23, and Youngstown, September 25.

Physicians Under Charges.—Dr. W. G. Hamlin, Bloomdale, charged with practicing medicine without a license, is said to have pleaded guilty to three charges and to have been fined \$25 and costs in each case. The fine is to be suspended in two cases providing the defendant quits the practice of medicine.—Dr. Robert S. Dunlap, Columbus, is said to have been arrested, July 30, on a warrant signed by Thomas Robinson, state drug department inspector, charged with the unlawful disposal of morphine.

Legal Duties of Physicians.—The state board of health is sending out information to all newly licensed physicians calling attention to the necessity of reporting all cases of inflammation of the eyes of the new-born, and of complying with the venereal disease regulations, which require reporting of all cases of venereal disease and instruction of all patients in the importance of guarding other persons against infection. The letter also gives full details in regard to the reporting of communicable and other diseases and outlines the free diagnostic facilities offered by the department laboratory.

Personal.—Dr. Harry H. Snively, Columbus, who was in charge of two base hospitals at Kiev, Russia, in 1915-1916, is a member of the Army Medical Expedition which has gone into Poland to combat typhus fever.—Charles W. Moors and P. Bruce Brockway, Toledo, and Verne A. Dodd and Frederick O. Williams, Columbus, Lieut.-Coms., U. S. Navy, have been promoted to the rank of commanders.—Dr. Arthur C. Taylor, health officer of East Cleveland for three years, has resigned.—Dr. Harold N. Cole, director of the bureau of social diseases of the department of health, Cleveland, has resigned, but will continue to serve in an advisory capacity.—Dr. Frances M. Hollingshead, Columbus, of the children's bureau of the state board of health has returned after service with the Child Welfare Bureau of France.—Dr. H. Nelson Amidon, Painesville, has been appointed coroner of Lake County succeeding Jotham F. Black, deceased.

PENNSYLVANIA

Personal. Dr. Joseph A. Buckwalter, Boyersford, was elected member of the board of directors of the Pottstown Homeopathic Hospital.—Dr. Edward E. Marsh, Centerville, recently returned, after service in Italy and France, has been elected superintendent of the Pottsville Hospital.

Measles Epidemic.—Jamison City, Columbia County, has an epidemic of measles. Two weeks ago every house in the

village was placarded. Physicians thought they had the disease under control and a number of the quarantines were lifted, but August 14, eighteen new cases developed.

Tuberculous Suffer from Lack of Milk.—Claiming that more than 300 tuberculous patients are being treated at the local state dispensary, and that many are in need of milk because the state appropriation is inadequate to furnish a sufficient supply, Dr. Christian Grubler, Shenandoah, made an appeal for the establishment of a fund to provide milk for about forty poor patients. The district comprises all towns north of the Broad Mountain. The work of the dispensary is handicapped by a shortage of milk, due to the inadequate state appropriation.

Philadelphia

Personal.—George S. Crampton, Lieut.-Col., M. C., U. S. Army, after fourteen months' service with the twenty-eighth division overseas, returned home, August 12.—Dr. Robert G. LeConte has received the cross of the Legion of Honor conferred on him by the French government.

Refuses State Funds.—Refusing \$22,000 appropriated by the state, the Frederick Douglas Memorial Hospital has opened a campaign to raise \$50,000. The recent legislature made the appropriation with the provision that Dr. Nathan F. Mossell, the founder, resign as superintendent and medical director. The board of directors refused to accept this condition.

Baby Welfare Workers Plan Convention.—A convention of baby welfare workers is being planned for the opening of the new dispensary and social service center of the Faber's Hospital of Philadelphia on the completion of the new building at Seventh and Delancey Streets. In the new building there will be a few hospital beds for emergency cases, but the scheme of the center is to have a dispensary and hold daily clinics. Laboratories for experimental and research work, social service rooms and a complete roof garden for the use of mothers and their infants during the hot season are parts of the plan for the new building. Dr. Charles A. Fife is president.

New Department of Public Health.—The new charter has so affected the department of public health and charities as to separate the health work from its charity functions. Under the terms of the new law, there is a department of public health of which the director of public health is the head, appointed by the mayor with the advice and consent of the council. He is to have the power to appoint an assistant director, and such other officers and employees as may be provided for. The department has the care, management, administration and supervision of city activities relating to public health including hospitals, control of housing and sanitation, and collection of vital statistics. The board of health is to consist of the director of public health, as president, and two other members, who shall be appointed by the mayor with the consent of the council. Two of the members of the board must be physicians.

TEXAS

Quarantine Station Transferred.—The state quarantine system of Texas will be transferred to the United States Public Health Service this month. The original proposition of the state fixed a minimum price of \$200,000 for the state quarantine property, but the individual appraisal made by the several state quarantine officers at their respective plants made an aggregate of \$166,000. This includes all quarantine property, including the buildings, ground, and the equipment for disinfecting and detention. Improvements to the station at Galveston are being made which will cost about \$40,000.

Personal.—The Hunt County Medical Society has adopted resolutions commending the labors of Major Charles E. Cantrell, Greenville, who was recently appointed district inspector-instructor in the United States Public Health Service with station at Corpus Christi. Major Cantrell was also presented with a gold headed umbrella. Major Cantrell's district includes the states of Texas, Oklahoma, Arkansas and Louisiana.—Dr. William P. Meredith has been appointed resident physician at the new Houston City Hospital.—Dr. Abner P. Howard has resigned as health officer of Vernon, and has been succeeded by Dr. Sunrow S. Greene.—Dr. H. C. Hall, acting assistant surgeon, U. S. P. H. S., Austin, has resigned as director of the bureau of venereal disease of the Texas Board of Health.—Dr. Frank N. Hagyard, San Antonio, who recently returned from France, has

been appointed surgeon for the International and Great Northern Railroad for the Taylor and Laredo districts.—Dr. Herbert F. Gammons has been appointed superintendent and medical director of Woodlawn Hospital, Dallas, the county sanatorium for Dallas County.

CANADA

Medical Associations.—The fourteenth annual meeting of the Alberta Medical Association will be held in Calgary, September 1 to 3, under the presidency of Dr. Daniel G. Revell, Edmonton.

Appeals from Action of Society.—On the ground that there is no evidence that he was convicted of an indictable offense, Dr. L. N. Cherniak, Windsor, whose name is said to have been stricken from the rolls of the Ontario Medical Society on account of having been fined for illegal use of liquor prescriptions, has taken an appeal against the action of the society.

Hospital News.—A medical clinic has been established at Dauphin, Man. It is the only medical clinic in Manitoba in which all the medical men are united.—Calgary, Alta., has planned a hospital scheme to cooperate with the militia of Canada. The hospital building at present under construction in Calgary is to cost about \$20,000. The city will build another extension if the government will cooperate, and is prepared to go to the extent of \$60,000. Should the government join in, Calgary will have its soldiers' hospital benefits centralized.—A new \$250,000 union hospital scheme is on foot for Moose Jaw, Saskatchewan, which is provided for in the Union Hospital Act of that province.

Public Health.—Edmonton, Alta., has been chosen as the place for the 1920 convention of the Canadian Public Health Association and Ontario Health Officers' Association. Dr. Heber C. Jaimeson, Edmonton, speaking recently on child welfare work, said that Alberta had considerably more trouble with the 33.6 per cent. of foreign-born children than with the remaining 66.4 per cent. British born, owing to the foreigners of that province holding to their traditions and refusing to adopt the methods in vogue in Canada.—Sixty per cent. of the inmates of jails in Manitoba are feeble-minded, according to a report of Dr. Clarence M. Hincks, Toronto, of the Canadian Mental Hygiene Commission. It is estimated that every incurable patient detained in the hospitals for the insane in that province costs the Manitoba government from \$5,000 to \$7,000.

Personal.—Col. Evans G. Davis, C. M. G., London, Ont., has been appointed A. D. M. S. for the Canadian Soldiers' Civil Reestablishment, in the place of Lieut.-Col. F. McKelvey Bell, Ottawa, Ont., resigned.—Major Thomas D. Archibald, recently in command of the Toronto Military Base Hospital, has reentered private practice in Toronto and will devote his attention to anesthetics.—Lieut.-Col. John M. Nettleton is now in charge of the Spadina Military Hospital, Toronto, but will shortly join the medical staff at Ottawa.—Brig.-Gen. Ernest C. Ashton, Brantford, Ont., is moving to Ottawa, where he has been appointed to a permanent position in the C. A. M. C.—Col. William B. Hendry, Toronto, lately in command of the University of Toronto Base Hospital, has been appointed associate professor of obstetrics and gynecology in the University of Toronto.—Prof. Andrew Hunter has been appointed professor of biochemistry in the University of Toronto, vacant through the resignation of Professor Robertson.

GENERAL

Personal.—Major-Gen. William C. Gorgas, U. S. Army, retired, chairman of the yellow fever commission of the Rockefeller Foundation, arrived in New Orleans, August 6, on his way to Salvador, Central America, where cases of yellow fever have been reported.

Missouri Valley Physicians to Meet.—The thirty-second annual meeting of the Medical Society of the Missouri Valley will be held in Des Moines, Iowa, September 18 and 19, under the presidency of Dr. Charles Wood Fassett, Kansas City, Mo. Headquarters will be at the Hotel Fort Des Moines.

New Naval Hospital.—July 24, the new Naval Hospital at Charleston, S. C., was thrown open for inspection. The hospital is situated north of the Navy Yard reservation, overlooking Cooper River, and has a capacity of 1,000 beds. The hospital was constructed under the supervision of Will M. Garton, Com., M. C., U. S. Navy, and has cost more than \$1,600,000.

Public Health Association Meeting.—The annual meeting of the American Public Health Association will be held in New Orleans, October 27 to 30, under the presidency of Dr. Lee K. Fraenkel, New York City. The central themes taken up will be, southern health problems, including malaria, typhoid fever, hookworm, soil pollution and the privy, etc., and there will also be discussions on the attitude of legislators toward public health, the securing of appropriations and cooperation for women's clubs, health organization, and the organization of health centers, and two special programs will also be presented on various phases of child hygiene and personal hygiene.

Requests and Donations.—The following bequests and donations have recently been announced:

Jewish Hospital Association, Philadelphia Jewish Sanitarium for Consumptives and the Federation of Jewish Charities, each \$500 by the will of the late Emma T. Losen.

Society for Improving the Condition of the Poor of New York, and Orphaned Children's Home, Utica, each \$1,000 by the will of Dr. John Henry Thompson, New York City.

Avesley Memorial Hospital, Chicago, \$5,000 by the will of Mrs. Sarah A. Pond, in memory of her late husband Walter M. Pond.

The creation of the Rosa Spang Foundation for the Relief of Poverty and Disease, and especially for the benefit of abandoned babies, \$1,000,000 by the will of Mrs. Rosa B. Spang, New York City.

Visiting Nurse Association of Chicago, to be used for the employment of nurses, a donation of \$12,500, by Bernard A. Eckhart.

License to Practice in All States.—A bill to license physicians under the federal government to permit them to practice in any state of the Union has been introduced by Representative Mason. The measure provides that any person who has taken a full four years' course in a professional medical school and who has been granted a state license, or any person who has been admitted to practice medicine and has practiced for at least five years, may obtain a license to practice in any state in the Union by paying a fee of \$10 to the Secretary of the Interior. The licensee must have his license recorded with the department of health in the state in which he intends to practice. The bill is numbered H. R. 8313, and it has been referred to the House Committee on Interstate and Foreign Commerce for consideration.

The Care and Treatment of Drug Addicts.—A measure appropriating a total of \$5,000,000 for federal assistance to the state health agencies for caring for and treating drug addicts has been introduced by Senator Joseph I. France, chairman of the Senate Committee on Sanitation and Public Health. The Secretary of the Treasury is authorized to divide the appropriation among the states, to be payable only if the respective states by official or private subscription raise a similar amount. The sum of \$3,000,000 is authorized to be expended before July 1, 1920, and \$2,000,000 is made available for the following year. One fifth of this amount may be expended to collect and spread information regarding the care and treatment of drug addicts. Any hospital equipment held by the army and navy which is not in use is to be transferred to the Treasury Department for the use of drug addicts. The Secretary of the Treasury is charged with the enforcement of the act.

FOREIGN

Hospital Opened in Siberia.—To meet an emergency of hospital work, for wounded Russians, the American Red Cross has opened a large hospital at Cheliabinsk under the care of Dr. Henry W. Newman.

Tuberculosis in French Soldiers.—In a discussion in the French Senate, July 12, it was stated that 25,000 French soldiers had died from tuberculosis during the war, and that 120,000 men had been exempted from service because of the disease.

Influenza in Portugal.—The *Medicina Contemporanea* of June 1, just received, states that the deaths from influenza at Lisbon during the preceding two weeks had been more than the total deaths from all causes during the preceding four months.

Achúcarro Prize Awarded.—The foundation of the prize in memory of Achúcarro, the Spanish histologist, was mentioned recently, June 7, 1919, p. 1690. As the first award, it has been given to the director of the laboratory of histopathology connected with the Junta de Ampliación de Estudios at Madrid, Dr. Pio del Rio Ortega. The prize is to be

awarded every two years and alternately to a Spanish and foreign histologist for the best work during the preceding four years.

Typhus Train.—A report of the Allied Antityphus Train, which has been operated in Siberia under the charge of Capt. Rudolph Bukely, under the direction of the American Red Cross, states that it has handled 20,000 men during the six months the train has been in operation. The reputation of the train as an effective weapon in fighting typhus is widespread.

Serbian Relief.—The medical section of the Red Cross Commission in medical and general relief work in Serbia is composed of eighteen physicians of the Medical Corps and Sanitary Corps of the Army under the direction of Lieut.-Col. Edgar E. Hume, M. C. U. S. Army, Frankfurt, Ky. One of the medical members of the commission died from pneumonia while on duty at Semendria.

Earnings of German Manufacturing Chemists.—The *Riforma Medica* states that the Farbwerke vorm. Meister, Lucius and Brüning firm at Höchst on the Main paid a dividend of 12 per cent. in 1918; in 1917 the dividend was 18 per cent. and in 1916, 25 per cent. The corresponding firm at Ludwigshafen paid out a dividend also of 12 per cent. in 1918; in 1916 the dividend rate was 20 per cent.

Relief Commission to Kuban.—A relief commission in charge of an American Red Cross unit has left St. Nazaire for the Kuban district of Russia to carry medical supplies, food and clothing for the needy civilians and soldiers in that district. The commission will carry a complete equipment for an army field hospital, and will be headed by Major Robert Davis, New York, and Capt. Henry Adams, Boston.

Fellowship of Medicine Forms Committee for Literature Interchange.—Under the authority of the Fellowship of Medicine of Great Britain, an Anglo-American committee has been formed, whose chief aim is to bring about a better interchange of medical literature of both countries. A committee has been formed in London to secure publication of American articles and to send British articles to American publications. It is announced that a similar committee is to be formed in America.

American Hospital in Great Britain.—The American Hospital for Great Britain was founded July 17 at a special meeting, in the Royal College of Physicians, the Earl of Reading presiding. A governing council with the American ambassador as chairman, was appointed, and two medical committees—one for Great Britain and the other for the United States—were constituted. The committee for the United States consists of Drs. George W. Cline, William J. and Charles H. Mayo, Albert J. Ochsner, Rudolph Alatas and Franklin H. Martin.

The Army Medical Department in the Victory Parade at Paris.—The *Bulletin Medical* of Paris relates that, for the first time in history, the chief of the medical department of the army was called to a place with the commander-general in the great victory parade. Médecin-inspecteur Toubert, aide-major général du Service de Santé, rode with the group of aides-majors généraux immediately following Maréchal Pétain. The students of the Military Medical Academy marched beside the students of the Saint-Cyr Academy, an institution like our West Point. Among the twenty-four medical students were many decorated with the insignia of the Legion d'honneur and all wore the fourragère with palms and stars. All these medical students had served in the front lines.

Congress of French Gynecologists and Accoucheurs.—For the second time, the official announcement is published that the First Congress of the Association des gynécologues et obstétriciens de langue française is to be held in the fall. The first time the date was set for Oct. 1, 1914, and the address had already been printed when the war broke out, and all contact with the war was dropped. The approaching meeting is to be held at Brussels, September 25, and the same subjects as before have been appointed for discussion. Every city in France with a medical school has a local society of gynecologists and obstetricians, and the federation of these societies with those of Latin Switzerland and Belgium forms the Association of French-Speaking Gynecologists and Accoucheurs. The subjects to be discussed are the biologic diagnosis of pregnancy; early release from bed after childbirth and operations; uterine cancer; preferred incision for laparotomies; medications and technique for hysterectomy in treatment of suppuration in the adnexa; and welfare work for pregnant and nursing factory workers.

LATIN AMERICA

Friction Between Druggists and Pharmacists.—Friction has been aroused between drug store owners and graduate pharmacists of Chile over a sanitary law pending in the chamber of deputies, under which the owners would be permitted to operate their business without the control of the pharmacists.

Yellow Fever.—Strict sanitary regulations and the prohibition of maritime traffic between the two towns and other ports, at La Unión, and San Miguel, San Salvador, have apparently checked an outbreak of yellow fever. Because of reports of the prevalence of yellow fever in Northern Peru, the board of health of Ecuador has closed all ports of that republic to vessels arriving from northern Peru.—An outbreak of yellow fever is reported from Piura, Northern Peru.

New Disease in Peru.—In the city of Piura there have occurred recently a number of cases of a suspicious disease. The cases so far have all occurred in the jail and there have been five deaths. There is some discrepancy of opinion among the local physicians, some of whom believe it is yellow fever while others think it is a new disease. All the patients have been isolated and the American physician who is in charge of the sanitary campaign at Lima has been requested to assume control of the epidemic.

PARIS LETTER

PARIS, July 24, 1919.

Congress of French Surgeons

The twenty-eighth congress of the Association française de chirurgie will open at Paris, at the Paris School of Medicine, Oct. 6, 1919, under the chairmanship of Dr. C. Walther. The questions proposed for discussion at the congress are: (1) closed traumatic lesions of the wrist; (2) surgical treatment of cancer of the tongue, and (3) paraneoplastic tumors.

Decrease in the Birth Rate

In his report on the number of children receiving charitable assistance in the department of the Seine, M. Rebeillard has pointed out the lamentable decrease in the birth rate. The number of births in the department of the Seine has decreased from 73,599 in 1911 to 47,480 in 1918. During the past year the number of abandoned children reached 3,149. Furthermore, the percentage of children turned over to the Assistance publique, according to the birth rate reports, has increased from 4.9 per cent. in 1911 to 6.63 per cent. in 1918, having reached the highest mark, 6.9 per cent., in 1916.

The situation is all the more grave owing to the fact that, at the same time, almost all the wetnurses have disappeared, which exercises a paramount influence on the increase in infant mortality, which for babies under 1 year has jumped from 10.66 per cent. before the war to 40 per cent. in 1918. The number of nurses that the Assistance publique was able to secure from the rural districts during the year decreased from 1,553 to sixty-five. In order to make up for this dearth of nurses, centers for artificial feeding have, to be sure, been established; but conditions are considered so deplorable that the government has begun on a new basis the rational organization of the feeding of infants.

With a view to bringing about an increase in the birth rate, the general council of the department of the Seine, at the instance of M. Emile Desvaux, has submitted the request that the legislature lower to 25 the age for attaining full matrimonial majority. (By matrimonial majority is meant the age at which one acquires the right of marrying without the consent of one's parents. In some countries, a written refusal signed by the parents is still required after one attains matrimonial majority, provided the marriage is opposed by the parents, before one is permitted, according to law, to proceed with the nuptials.—Ed.)

Congress of French-Speaking Gynecologists and Obstetricians

The Association des gynécologues et des obstétriciens de langue française will hold its first congress in Brussels, Sept. 25-27, 1919, under the patronage of the king and queen of Belgium. The meetings will be held in Parc Léopold, at the Institute of Physiology.

The Organization of Physical Education

In order to promote the use of gymnastic exercises among the youth of the land, the president of the Conseil des ministres has adopted various measures with a view to securing the cooperation of the army and the heads of public instruction. With this idea in mind the council has addressed a

circular to the regional commanders and to those in charge of centers for physical instruction, including military preparatory schools. In this circular the order is given to grant to teachers and pupils free access to regional centers, and provision is made for the installation of vacation camps and for the organization throughout the entire territory of vacation courses in physical education.

Vaccination Against Smallpox

In a preceding letter I called attention to the epidemic of smallpox which occurred recently in Paris (*THE JOURNAL*, Aug. 2, 1919, p. 350). The prefecture of the department of the Seine has again called the attention of the public to the necessity of being vaccinated against smallpox. Every week, in the different sections of Paris, free vaccination is offered. Posters about the city indicate the time and place for securing vaccination.

A Gift to the Museum of Natural History

The Jardin des plantes de Paris and the Muséum d'histoire naturelle, owing to the lack of sufficient appropriations, have not kept pace with the needs of the times, and the buildings at their disposal are unworthy of their renown and of the place that they hold among scientific institutions by reason of their rich collections. The Société des amis du muséum, the president of which is M. Léon Bourgeois, former president of the Conseil des ministres, has been founded for the purpose of working toward the rehabilitation of the Jardin des plantes, the adjoining museums, the galleries, the research laboratories and the courts which go to make up this grand national institution. M. Basile Zaharoff, desiring to aid in this work of rehabilitation, has made a gift of 500,000 francs to the Muséum d'histoire naturelle, to be used in its restoration, enlargement and improvement.

An American Woman the Recipient of the Decoration of the Legion of Honor

Dr. Louis Mourier, undersecretary of state for the army medical department, has bestowed on Miss Bishop the cross of a knight of the legion of honor. Since the beginning of the war this energetic American woman has given France unlimited proof of her intelligence in the administration of welfare work. Since 1916 she has been employed in the hospitals outside of Paris in the care of the wounded. In 1917 she established in Paris a foyer du soldat for the "on leave" men from the invaded districts. At Soissons she was instrumental in installing a hospital under a terrible bombardment. After the signing of the armistice she organized relief stations at Cambrai. At the present time she is still engaged in the devastated regions relieving, where possible, misery and distress.

Death of Dr. Demoulin

From Saint-Lon (department of Landes) news has come of the death of Dr. A. Demoulin, a Paris hospital surgeon and consulting expert of the tribunal civil de la Seine.

Personal

Dr. Maillard, professor of pathologic chemistry at the Paris School of Medicine, has been appointed professor of biologic chemistry at the Alger School of Medicine and Pharmacy.

M. Paul Appell, dean of the Faculté des sciences de Paris, has just resigned the duties of the office that he has held for sixteen years. He has been succeeded by M. Housay, professor of zoology of the Faculté des sciences de Paris.

Dr. Policard, professor on the faculty of the Lyons School of Medicine and Pharmacy, has been appointed professor of general anatomy and histology in the same institution, in place of Professor Renault, who has been allowed to take advantage of his right to retire.

Dr. Mouriquand, professor on the faculty of the Lyons School of Medicine and Pharmacy, has been appointed professor of general pathology and therapeutics in the same institution, in place of Professor Lesieur, deceased.

American Students in French Universities

More than 5,000 American officers and private soldiers have pursued courses in French universities during the past few months. The American soldier-students have recently given expression, in a delicate manner, to their gratitude to their French instructors. They have raised by subscription among their number more than 70,000 francs. This sum is to be divided among the fourteen French universities that have received American students. At the opening of school in the fall fourteen French students will sail for the United States, where they will pursue a course of study for a year at some American university.

Child Welfare

L'Institut de puériculture, of the founding of which I have already spoken in a previous letter, a project which owes its origin to the gift of 1,000,000 francs from the American Red Cross and a like sum raised by subscription in Paris (*THE JOURNAL*, June 14, 1919, p. 1781), met recently at the Paris School of Medicine for the purpose of organizing a permanent society. M. Lucien Poincaré, rector of the University of Paris, presided at the meeting, being assisted by Professor Roger, dean of the Paris School of Medicine, M. Mesuranc, director of the Assistance publique, and nearly all of the faculty of the Paris School of Medicine. Dr. Kenneth Wygatt represented the American Red Cross. After an address by Professor Roger, in which he pointed out what part the School of Medicine was expected to play in this undertaking, Professor Pinard, in a few words, gave expression to his great joy in seeing realized an idea which he, conjointly with all the gynecologists and pediatricians of France, had supported for so long. It should be stated in this connection that the Children's Welfare League of America has contributed to the institute the sum of 500,000 francs.

The Campaign Against Tuberculosis

The senate has recently passed the bill establishing special sanatoriums for the treatment of tuberculosis and fixing the conditions for the admission of patients (*THE JOURNAL*, April 12, 1919, p. 1092). The bill provides that the state, under certain guaranties, will assume the expense of establishing these sanatoriums, and it is thought that these state establishments will set a good example for private institutions.

LONDON LETTER

LONDON, July 25, 1919.

British Versus German Science

At the annual meeting of the Society of Chemical Industry, Prof. H. Louis, the president, stated in his address that the one great fact that emerged from the war was that our chemical industry had shown itself capable of sustaining successfully the fiercest and most strenuous competition. Utterly unprepared for war conditions, it had shown itself more resourceful, more energetic, and more successful than any had dared to hope. We could never have built up so rapidly this vast edifice of chemical industry if the foundations on which we had to build had not been thoroughly sound. He saw in these results a triumphant vindication of the thesis that in the teaching of science, and more particularly of scientific technology, we were quite on a par with any other nation. It had often been urged by those who looked on German educational methods as the acme of perfection that we ought to model our methods of technical teaching on German lines. This war had shown that our teachers, who had steadfastly adhered to the methods that suited our national idiosyncrasies, were justified. We could certainly learn much of the organization of scientific education and much of the respect due to science from our enemies, but we should adhere to our own essentially British methods of technical education. Germany had for forty years been applying her science to warfare, but the science which we possessed available for such application was of a far higher order, and we had been able to beat our enemies at all points. We had beaten Germany in war because of our superior productivity; we produced more of the essentials needed in warfare than did our enemies—more ships, more guns, more explosives. What was true of warfare was equally true of the less spectacular but no less severe competition of peace; if we were to hold what we had gained, it could only be by maintaining our productive capacity and increasing our outputs. This was a task that could not be accomplished by scientists and technologists alone; they could but devise and organize the methods by which the work was to be done; but they must call on the body of workers of the country to execute them. He had worked in many lands and had employed men of many different races and different nationalities, and he could say without hesitation that the British working man had no superior as a workman, if he only chose to work, and he therefore saw no reason why he should produce less effectively than any of his competitors.

Mothercraft

At the National Birth Rate Commission, Dr. Eric Pritchard gave evidence that 26 per thousand infants were born with malformations and physical defects of development which

rendered the satisfactory carrying out of the functions impossible. The remaining deaths out of the total number, namely, 70 per thousand births, were due to causes that could not be referred to any demonstrable defects at the time of birth. About 40 deaths per thousand births were attributed to infectious diseases of one kind or another. The remaining deaths were due to miscellaneous diseases, including a large number under the classification of wasting, debility and marasmus. Infections were responsible for much the largest number of the deaths during the first year of life. A much larger number of infants died from unrecognized infections than was usually believed. New-born infants could not defend themselves against a large number of quite simple organisms to which older individuals were completely immune, or of which they might be the "carriers" without detriment to themselves.

Good mothercraft, which practical experience proved to be efficacious in preserving the life of the infant, was knowingly or unknowingly designed to preserve the natural defenses of the body against bacterial invasion, or to maintain or raise the degree of tissue immunity. The artificially fed infant more easily fell a victim to vicarious infection. Further, by the damage inflicted on the digestive tract by unsuitable foods, before the digestive organs had developed their normal functions, the infant was exposed to the entrance of organisms through the areas of lessened resistance. Artificially fed infants, and especially those fed on patent foods containing a great excess of sugar, were notoriously non-resistant to infectious disorders. The sources of infection were even in the best circumstances manifold, but in slum areas where the infants shared the same room with several other individuals, these dangers were greatly magnified.

Dr. Halford Bross, late health officer, Suez Canal Zone, also gave evidence. He said that from observations in that zone it would seem that there was a constant correlation between birth rates and death rates. As one increased, the other increased; if one was reduced, the other fell. In a certain place a serious epidemic of plague occurred in 1907. The death rate rose higher than the birth rate for three weeks, but soon the birth rate rose and regained its former relation with the death rate, which remained high for a time. Then both fell together to their original level as soon as the plague disappeared. A similar correlation of birth rate and death rate was noticed in Cairo in 1910 during a severe fatal outbreak of smallpox. This correlation of births and deaths made any measures taken to modify their rates appear futile, because their relation seemed to follow a natural law, which at present was not understood. Our aim, then, should be to prevent all disease, so that infants when born were healthy and remained healthy through life. In that way the most efficient population could be obtained.

Medical Certificates of Fitness for Marriage

At a conference on public health, Sir Malcolm Morris recently expressed the view that no marriage ought to take place without a medical certificate on both sides. But it is doubtful whether prevailing sentiment would allow this to be carried out. Interviewed on the subject by a representative of the *Daily Sketch*, Sir Malcolm stated that to a certain extent it was adopted in America, and that there were few instances of the kind in this country. But if public opinion set up such a custom in this country, then the medical profession would require legislative protection. If a physician, after examining a patient, had to advise the parents of a girl that it was not advisable for her to marry him, then protection by law would be necessary.

Although Sir Malcolm Morris does not suggest that there should be legal enactment, making the issue of such certificates imperative, Dr. Neal, the secretary of the Medical Defence Union, thinks it would be utterly impossible to bring about legislation of this kind. "While from a medical point of view such a step might be desirable, on sentimental and other grounds, there is something very repugnant about the idea," he remarked. "Just imagine the feelings of a decent young man at the very suggestion, on the part of his parents, that he must obtain a certificate that his prospective bride is free from disease! It would not be merely a gross reflection on her purity, but would imply that she was a woman of very abandoned type."

Experimental Medicine and the War

At the annual meeting of the Research Defense Society, Sir Anthony Bowley, consulting surgeon to the British armies in France, spoke on experimental medicine and the sick and wounded in war. The British army had been the healthiest of all the armies engaged; its sick casualty was less than any other. The reasons were, in the first place, that the average

man in this country was a cleanly animal, and understood and followed advice which was evidently reasonable; and, in the second place, the army medical service, as a body of experts trained in hygiene and preventive medicine, was unequaled in any country. Every one was aware of the small incidence of typhoid fever in the war, but there were people who were trying to explain away the value of the prophylactic inoculation by saying that the comparative freedom from typhoid was due to improved hygiene. Even were this true, the fact would remain that the hygiene of today was as based on the experimental medicine of yesterday; but preventive inoculation was to a large extent the real cause of the immunity. This was proved by the unfortunate instance of the French troops who, in the early days of the war, hurrying to save their frontier, went out uninoculated. The result was that between August, 1914, and the following April there were as many cases of typhoid in the French army as were recorded in the South African war. The strength of the army was wasted to the extent of 60,000 men. The great prevalence of tetanus was not anticipated at the beginning of the war, so that at first the supply of prophylactic serum was not proportionate to the number of troops. Supplies of antitetanic serum were obtained as quickly as possible, and by the end of October, 1914, large quantities became available. Its value was shown by the fall in the ratio of tetanus cases to the number of wounded. The ratio in September, 1914, was six times as high as it became in November, and nine times as high as it became in December. A hook might be written on experimental medicine which had been actually developed during the war. A great deal had been learned with regard to gas gangrene, in particular that three organisms were concerned, which accounted for the comparative failure of serum treatment. Toward the end of the war a trivalent serum was produced which, in the opinion particularly of the French authorities, was of great value, although it did not do enough. Valuable work on the mode of dissemination of trench fever was done as a result of the action of British and American volunteers, who subjected themselves to the attack of infected lice. Much had been learned also with regard to dysentery, both the amoebic and the bacillary form; it was found possible to prevent spread and to expedite cure. Dysentery first developed in the British army as a result of the success of the Battle of the Somme in 1916, when the men entered the territory which had been occupied by Germans suffering from the disease. In conclusion, Sir Anthony mentioned the discovery of filter-passing organisms by Sir John Rose Bradford and Captains Wilson and Bashford. He had no doubt whatever that this discovery would throw a flood of light on the whole of the zymotic diseases encountered in civil life.

Army Medical Memorial Service

A service in memory of the 568 officers and 4,634 other ranks of the Army Medical Corps who gave their lives in the service of the country during the war has been held at St. Paul's Cathedral. Among those present were Princess Helena (representing Princess Christian); Princess Louise, Duchess of Argyll; Princess Beatrice; Col. Sir H. Straatfield (representing Queen Alexandra); Sir John Goodwin (Director-General); Lieut.-Gen. Sir Alfred Keogh; Lieut.-Gen. Sir Lancelot Gubbins, and Lieut.-Gen. Sir Arthur Sluggott. Selections played by the Grenadier Guards included the "Marche Funebre et Chant Serephique" (Guilmant); the "In Memoriam" Overture; Massenet's "Benedicta," and Beethoven's "Egale." The buglers of the Army Medical Corps sounded the "Last Post" and the "Reveille."

Marriages

EDWARD AUGUSTINE STAVELTON, Albany, N. Y., to Miss Sarah Gertrude McGowry of Wilkes-Barre, Pa., at Greenwich, August 2.

ROBERT FINLEY GAYLE, JR., Lieut., M. C. U. S. Army, New York City, to Miss Elizabeth Marshall Cole of Raleigh, N. C., August 16.

FRED DEFOREST STREETER, Central Islip, N. Y., to Miss Alice Sherwin of Manchester, Vt., July 25.

HERMAN CARL JUNGLOUT to Miss Johanna Stehn, both of Tripoli, Iowa, recently.

RICHARD AMBERSE ROOHE to Miss Ruth Wilkie, both of Chicago, August 6.

Deaths

Otto Augustus Wall, Jr. * St. Louis; Missouri Medical College, St. Louis, 1898; aged 45; associate professor of materia medica and pharmacognosy and lecturer on accidents and emergencies in the St. Louis College of Pharmacy; associate medical director of the International Life Insurance Company, St. Louis; at one time editor of the *Weekly Bulletin of the St. Louis Medical Society*; died in Barnes Hospital, St. Louis, August 4, from heart disease.

Henri Michel Auger, Jamaica, N. Y.; University of Buffalo, N. Y., 1886; aged 62; for several years physician to the Jamaica Board of Health and assistant medical examiner for the Long Island Railroad; one of the founders of St. Mary's Hospital, Jamaica, and a member of the staff of the Jamaica Hospital; died at his home, August 5, from rheumatism.

John Francis Bourke * Lieut., M. C., U. S. Army, Jamaica, N. Y.; College of Physicians and Surgeons in the City of New York, 1905; aged 39; post surgeon at Southern Field, Americus, Ga.; formerly instructor in diseases of the digestive system in Fordham University, New York City; died in his office at Southern Field, July 28, from cerebral hemorrhage.

Franklin S. Bower, Philadelphia; College of Physicians and Surgeons, Baltimore, 1881; aged 60; first president of the North Philadelphia, afterward the Samaritan Hospital, Philadelphia; a member of the Medical Society of the State of Pennsylvania; died at his home in North Philadelphia, August 1, from nephritis.

Joseph W. Applegate, Green Cove Springs, Fla.; Jefferson Medical College, 1862; aged 84; surgeon of U. S. Volunteers during the Civil War; for many years a druggist of Franklin, Ind.; for thirty-five years owner and manager of a hotel at Green Cove Springs; died at his home from ciliary dysentery.

William H. Aber, Annyville, Mo.; Beaumont Hospital Medical College, St. Louis, 1897; aged 49; a member of the Missouri State Medical Association; while driving his automobile over a grade crossing at Higginsville, Mo., August 2, was struck by a Chicago and Alton train and instantly killed.

J. Lindsey Hill, Albany, Ore.; Willamette University, Salem, Ore., 1871; aged 74; for several years an instructor in his alma mater; at one time mayor of Albany; founder and president of a local insurance society known as the "Twenty-Five Hundred"; died at his home, August 3.

Charles E. Hansel * South Bend, Ind.; University of Illinois, Chicago, 1897; aged 45; a member of the Central Pediatric Society; president of the board of health of South Bend; died suddenly at the South Bend Country Club, August 3, from heart disease.

Daniel F. Gleason, Brooklyn; Jefferson Medical College, 1875; aged 62; formerly chief inspector for the Brooklyn Board of Health; for the past fifteen years a detective for the Pinkerton Agency; died at his home, August 3, from heart disease.

William Cecil Leavenworth * Augusta, Ga.; University of Virginia, Charlottesville, 1917; formerly acting superintendent of Johns Hopkins Hospital, Baltimore; superintendent of the University Hospital, Augusta; died, July 29.

Jacob F. Marchand * Canton, Ohio; University of Pennsylvania, Philadelphia, 1887; aged 61; surgeon to the Altman Hospital for twenty years; consulting surgeon to Mercy Hospital; died at his home, July 31, from diabetes.

Mary Elizabeth Stanford, Chicago; Chicago Physio-Medical College, 1897; aged 53; professor of physiology in the Chicago College of Medicine and Surgery; died at her home, August 14, from myocarditis.

Charles Frederick Miller, Los Angeles; University of California, San Francisco, 1874; aged 71; a member of the Medical Society of the State of California; died at his home, July 22, from senile debility.

Samuel Trimble, Lima, Pa.; University of Pennsylvania, Philadelphia, 1897; aged 70; a member of the Medical Society of the State of Pennsylvania; died at his home, August 7, from disease of the kidney.

Frederick Chandler, Mechanic Falls, Me.; Bowdoin Medical School, Brunswick and Portland, Me.; 1877; aged 67; died at his home, June 10, from arteriosclerosis.

Thomas Muttter Allison, Kittanning, Pa.; Jefferson Medical College, 1872; aged 70; a member of the Medical Society of the State of Pennsylvania; died at his home, June 3, from pulmonary tuberculosis.

Edric Allen Wade, Salem Depot, N. H.; Harvard University Medical School, 1879; aged 68; died in the Massachusetts General Hospital, July 19, following operation for the removal of gallstones.

Clarence T. Lewis, Staunton, Va.; George Washington University, Washington, D. C., 1878; aged 66; a member of the Medical Society of Virginia; died at his home, July 19, from tuberculosis.

John Howard Sherman, Boston; Castleton (Vt.) Medical College, 1857; aged 88; for several years medical inspector in the public schools of Boston; died at his home in South Boston, August 2.

James Moon Salmon, Simcoe, Ont. (qualification, 1847, medical board, Kines College, Toronto, Ont., license, Toronto, 1866); aged 95; died at his home, June 17, from arteriosclerosis.

Algeron M. Sargent * Lincoln, Ill.; Medical College of Ohio, Cincinnati, 1880; aged 62; a director in the Lincoln National Bank; died at his home, August 3.

James E. Glenn * Fairfield, Pa.; College of Physicians and Surgeons, Baltimore, 1891; aged 53; died at his home, August 4, from cerebral hemorrhage.

Lauren Milton Lindenberger, Troy, Ohio; Bellevue Hospital Medical College, 1880; aged 69; died at his home, in Troy, July 23, from angina pectoris.

George M. Ross, Schell City, Mo.; Missouri Medical College, St. Louis, 1883; aged 58; died in Moundville, Mo., May 23, from cirrhosis of the liver.

Aaron C. Vaughan, Rockford, Ohio; University of Pennsylvania, Philadelphia; 1858; aged 83; died at his home, about July 17, from senile debility.

George Gregg, Ashland, Ohio; Western Reserve University, Cleveland, 1868; aged 80; died at the home of his daughter in Ashland, August 3.

Rufus Henry Allen, Nashville, Tenn.; University of Nashville, Tenn., 1900; aged 40; died in an infirmary in Nashville, August 5, from pneumonia.

William Smith Mecklem * Mansfield, Ohio; University of Wooster, Cleveland, 1880; aged 57; died at his home, July 28, from cerebral hemorrhage.

Frederick John Kruell * Hollywood, Los Angeles; Rush Medical College, 1881; aged 66; died at his home, July 29, from cerebral hemorrhage.

James A. Houser, Indianapolis; Toledo (Ohio) Medical College, 1880; aged 72; for forty-five years a practitioner; died at his home, July 29.

John Newton Moorman, Cross Plains, Texas; University of Nashville, Tenn., 1869; aged 82; died at his home, April 30, from senile debility.

Daniel Graham Carey, Elmira, N. Y.; Eclectic Medical College of Pennsylvania, Philadelphia, 1870; aged 79; died at his home, August 2.

John W. Moose, Agnes, Texas; College of Physicians and Surgeons, Baltimore, 1880; aged 66; died at his home, May 12, from diabetes.

Martin J. Crockett, Sylvester, Ga.; Eclectic Medical Institute, Cincinnati, 1870; aged 72; died at his home, May 2, from epithelioma.

Eli Edwin Graves * Pennecook, Concord, N. H.; University of Vermont, Burlington, 1868; aged 72; died at his home, August 5.

James F. Lockett, Okemah, Okla.; Iowa Medical College, Keokuk, about 1859; aged 86, died at his home, June 25, from senile debility.

John L. Buxton, Bell City, Mo.; Eclectic Medical Institute, Cincinnati, 1888; aged 58; died at his home, July 25, from tuberculosis.

Lauren A. Stillman, Chicago; Loyola University, Chicago, 1891; aged 62; died at his home, August 8, from arteriosclerosis.

Samuel C. Moore, Urbana, Ohio; Cincinnati College of Medicine and Surgery, 1870; aged 74; died at his home, July 27.

William H. Sampson, Ashland, Ohio; Jefferson Medical College, 1876; aged 69; died at his home, July 23, from uremia.

The Propaganda for Reform

IN THIS DEPARTMENT APPEAR REPORTS OF THE COUNCIL ON PHARMACY AND CHEMISTRY AND OF THE ASSOCIATION LABORATORY, TOGETHER WITH OTHER MATTER TENDING TO AID INTELLIGENT PRESCRIBING AND TO OUTWIT MEDICAL FRAUD ON THE PUBLIC AND ON THE PROFESSION

CAPELL'S UROLUETIC TEST

U. S. MARINE HOSPITAL, Chicago.

To the Editor:—A member of the consultant staff of this hospital recently referred to us a "Doctor" H. F. Matthews, who was supposed to give demonstrations of a new test for syphilis—"Capell's Uroloetic Test." The test was to be made of the urine of the patient. The above mentioned consultant was under the impression that the said "Doctor" Matthews was a graduate physician.

"Doctor" Matthews came to the hospital according to the appointment made by the consultant, and proceeded to give his demonstration. Several of the junior officers and interns were present to witness it. He was asked questions in an attempt to determine the scientific status of the test which he was demonstrating. His answers were always vague and indefinite and not clothed in scientific words.

We became suspicious of him, and he was asked if he was a graduate physician. He admitted that he was not. He was further asked if he had studied chemistry and bacteriology; he stated that he had in 1888. Inquiry was made as to where; he replied that it was at the University of Illinois. He was further asked if he was familiar with the Wassermann reaction. He stated that he was not.

This man is going around representing himself as a physician who has a new test which he claims is superior to, and more delicate than the Wassermann test; yet he knows nothing whatever of the technique of the Wassermann reaction.

In one case, we gave him the same specimen of urine in four different containers. He read a different degree of reaction for each of them. In other words, in a specimen from the same patient, his four different tests showed, respectively, a +, a ++, a +++ and a ++++ reaction.

It occurred to me that it might be well to inform you of this man's methods, as he told us that he had been to a good many institutions, and I am sure he will soon start a plan to systematically force his pseudoscientific test on credulous physicians everywhere.

J. O. Cobb, M.D., Senior Surgeon in Charge.

The Propaganda Department has in its files a business card reading: "Capell's Laboratories, Room 1510 Masonic Temple, Chicago. Dr. H. F. Matthews, Special Representative." Capell's Laboratory has its headquarters in Omaha, and is apparently conducted by Dr. W. L. Capell, who, for many years, seems to have been more or less interested in proprietary medicines. Some years ago he was connected with a concern known as "Aeneine Pharmaceutical Company," which, apparently, was dissolved some time in 1910, and soon thereafter a new company was organized known as the Leboy Drug Company. In 1917 W. L. Capell was connected with the Capell, Cameron Co., Inc., of Lincoln, Neb., which was selling "Capell's Uroloetic Test," "Capell's Treatment for Syphilis" and other remedies. The "Treatment for Syphilis" was said to be:

"Painless, Pleasant, Harmless, Efficacious, and requires usually from 30 to 90 days only to eradicate the disease."

The name of the treatment is "Mercurodin," earlier it was called "Ganin" and it is now being sold from "Capell's Laboratory," Omaha. In addition, Capell's Laboratory sells Aeneine, which apparently is the same product that was sold in 1906 and 1907 under the name of "Sambin-Co" by the Holtman-Stringer Co. of Omaha and later was put out by the Aeneine Pharmaceutical Company of Omaha.

While Capell's Laboratory sells proprietary remedies, it is the "Uroloetic Test" which the concern now seems to be featuring. The claims made for this are:

"This test requires no expert knowledge, is inexpensive, and can be made in a few minutes, and is so plain that it cannot be mistaken."

The idea of being able to determine the absence or presence of syphilis by a simple color test of the urine, is a fascinating one. The present reliable diagnostic tests are, as Capell's Laboratory so plausibly emphasizes, somewhat involved, and call for rather delicate technique. But there are no short-cuts to knowledge.

A physician who ordered Capell's Uroloetic Test some weeks ago received with the bill the letter that follows: It is given not so much for what it says, as for how it says it. It is copied *verbatim et literatim*:

"Your letter received, and we have mailed you as per your letter 1 Doz. of Capell's 'Uroloetic' Tests. In close find statement and instructions, for same."

"The 'Uroloetic' Test is meeting a far greater approval from the Medical profession than we had expected, while we do not claim that it is perfect, yet we have only received one unfavorable report, and we daily feel incured in its efficacy."

"You know Doctor that there are two dangerous elements in this world, one is the extreme pessimist and the other is the extreme optimist. The immoral Lincoln said, 'That there was nothing that was wholly good or wholly evil,' and we presume that this is equally true of the 'Uroloetic' test. But we want the truth no matter what it is."

"Capell's Uroloetic Test" would be "important if true." Unfortunately, its scientific value to the sufferer is negligible compared with its economic value to the exploiter. It is not so much a test for lues in the patient as of credulity in the doctor.

Correspondence

"H. M. C." AND DRUG ADDICTION

To the Editor:—The more or less discredited "twilight sleep" has been largely applied in this country through the medium of a proprietary tablet known as "H. M. C." and composed of "hyoscin" (scopolamin) morphin and cactin. The cactin is negligible in the formula, and the product would probably be improved were it omitted from the mixture; but "H. M. C." is a name readily remembered, and the product must be credited with marked activity.

That this proprietary might be habit-inducing did not occur to me until recently, when I noticed from our drug reports how frequently prescriptions for original packages of it appear. A certain degree of tolerance to scopolamin is produced, but it is not generally regarded as habit-inducing. It appears in our work, however, that an addict to heroin will readily come to tolerate quite considerable doses of scopolamin and, indeed, the heroin addicts when deprived of their drug are fairly well content with scopolamin as a substitute. Both drugs depress the respiratory center very markedly and often lead to collapse.

Western Pennsylvania seems to have a great incidence of asthma, and it is here and in this disease that "H. M. C." tablets are coming into vogue, I believe very unwisely.

I have noted eight cases in the city of Erie in which prescriptions of original packages of "H. M. C." have been given—six of the patients being men and two women, and the quantities ranging from twenty-five to 100 tablets. Doubtless some of the smaller prescriptions were written by physicians when in attendance in obstetric cases, a proper number being used and the physician taking the remainder back to his office; but 100 would hardly be prescribed under such circumstances.

I believe this was the disposition of prescriptions noted as written in Corry and also in Washington, though in the latter place one woman had prescribed for her 183 tablets in the course of three months. Scattered reports throughout western Pennsylvania show many persons receiving from fifty to 200 tablets. Most of them are sufferers from asthma of some type.

In a most distressing case of chronic asthma, in the family of a physician in Lawrence County, the patient some weeks requires one tube of "H. M. C." and the good doctor writes me: "We have sent her to the following cities: Pittsburgh, Cleveland, Elwood, Youngstown and Kane, to the best physicians; and always it was the same old treatment, viz., 'H. M. C.'" This report leads me to believe that the use of these tablets in asthma is rather common.

But the most striking case is reported from Jefferson County. The patient, a male morphin addict, somewhat advanced in years, has taken "H. M. C." for four years, gradually running up the dosage. He also has asthma. In the course of a long letter this man writes: "I have far over one hundred dollars' worth of tubes that Dr. ——— prescribed here now empty, and Lord only know how many more I throw away."

Some of the cases we encounter tend to show that marked tolerance can be established to scopolamin, especially in a morphin or heroin addict; and, without implying any belief that the makers of the "H. M. C." tablet would promote its improper use, I believe that physicians should be most careful in supplying this potent alkaloidal mixture to their patients.

THOMAS S. BLAIR, M.D., Harrisburg, Pa.
Chief, Bureau of Drug Control, Pennsylvania Department of Health.

RELATIONSHIP OF INFLUENZA BACILLUS TO INFLUENZA

To the Editor:—The relationship of *Bacillus influenzae* to influenza is, at present, a subject of such great importance that I trust you will permit me to draw attention to a statement of Dr. W. H. Park in his article on "Bacteriology of Recent Pandemic of Influenza and Complicating Infections" (THE JOURNAL, Aug. 2, 1919, p. 318). Dr. Park says: "Although Keegan, Opie and their associates believe that the influenza bacilli are the causative agent, they present no real evidence." I have published no dogmatic opinion concerning the relationship of *Bacillus influenzae* to the disease because I have not believed that the data available justified a definite conclusion. The report of the commission of which I was a member (THE JOURNAL, Feb. 22, 1919, p. 556) contains evidence that *Bacillus influenzae* has been found in every instance of influenza which the commission studied by appropriate methods; but the significance of this observation is not discussed in the report. Dr. Park says: "They place the sequence of events as follows: At the time of infection, *B. influenzae* descends into the bronchi; later, pneumococci may invade the inflamed bronchi," etc. This statement doubtless paraphrases the following: "The sequence of events in many cases of influenza is as follows: *B. influenzae* descends into the bronchi; pneumococci invade the inflamed bronchi," etc. There is, here, no reference to the etiology of influenza; the bacteriology of the bronchitis and pneumonia of influenza is under discussion. Dr. Park dismisses with a few words the complex subject of influenza bacillus carriers. With the many defects in present knowledge of the micro-organism and of the disease, an expression of opinion concerning the relation of one to the other would require obvious qualification. It is the purpose of this letter to state that the conclusion which Dr. Park finds so available is inferred from the report by himself and is not mine.

E. L. OPIC, M.D., St. Louis.

IS GONORRHEA INCURABLE?

To the Editor:—The doctrine that gonorrhea in the male is incurable seems, for certain reasons, to be gaining ground among physicians and laymen alike. As one of those who dissent from this belief—which, if erroneous, is fraught with harm—I desire to emphasize the distinction between *incurable* and *uncured*.

To physicians of the last generation gonorrhea was a "urethritis" only; invasions of extra-urethral structures were "complications." So long as pus issued from the meatus it was assumed to be produced in the urethra; and this innocent canal was tortured with caustics, dilators, knives and urethrosopes without avail. Today we know that the disease is usually urethrovaginitis, the infection invading vesicles and ampullae in from three to twenty days after the discharge appears; and that from these extra-urethral cavities pus may drain into the urethra and out of the meatus for two or twenty years in spite of any or all treatment of the urethra; for this merely mops up the floor, the urethra, without turning off the faucets, the vesicles.

These numerous cases are uncured but not necessarily incurable; for there is now ample evidence from many sources that a single filling of the vesicles with collargol solution (by vasotomy) has promptly cured many of them. Failure to cure some by one injection has led to the evolution of vasotomy into vas-puncture, analogous to puncture of a vein, whereby the vesicle can be repeatedly filled without the drawbacks of an operation. The possibilities of such treatment were illustrated by a man in the third week of severe gonorrhea whose vesicles were filled with collargol solution in St. Luke's Hospital, in April, 1914. He was apparently well on the fifth day thereafter, submitted seminal fluid found to be free from gonococci on the ninth day, and married his nurse on the fifteenth day after operation, without subsequent evidence of gonorrhea in either person.

The ancient belief in the incurability of gonorrhea, based on the obsolete idea that the disease is urethritis only, seemingly needs revision by the modern demonstration that acute gonorrhea is commonly urethrovaginitis, requiring early treatment of vesicles as well as of urethra.

WILLIAM T. BELFIELD, M.D., Chicago.

DEATH FROM RHUBARB LEAVES DUE TO OXALIC ACID POISONING

To the Editor:—I enclose herewith a case history reported by Dr. Harry J. Robb of Broadview, Mont. I should be interested in having your opinion on Dr. Robb's diagnosis of this case.

JOHN J. SUREY, M.D., State Epidemiologist,
Helena, Mont.

On the morning of May 6, Mrs. A. made breakfast, but at the time did not feel well. She then went to bed where she remained. She began to have cramplike pains in the abdomen during the forenoon. These pains continued intermittently all day until 12:30 a. m., May 7. I was called to see her, and arrived at her home, 20 miles away, at 1:30 a. m., May 7. At that time she was very weak and pale, and so drowsy that it was difficult for her to answer any questions intelligently.

Her temperature was normal. The respirations were 36 a minute. The radial pulse could not be felt. The heart beat was 120 a minute. The extremities were cold. She could keep nothing in her stomach, and vomited a brown, bloody fluid. I found the complete products of conception of about six weeks' development, discharged into the bed. The placenta was bloodless, and a small amount of blood discharged with it did not coagulate after several hours.

Heat to the body and stimulants gave no improvement, and her condition continued to become worse until her death, a few hours later.

After death there was considerable bleeding from the nose. This blood failed to coagulate.

I learned from Mr. A. that she had not taken any drugs except a couple of acetylsalicylic acid tablets, which she took that day for her pain.

May 5, Mrs. A. prepared some rhubarb for supper. The leaves were fried for greens and the stalks were boiled. She ate most of the leaves herself and seemed to relish them. Mr. A. took a spoonful of the leaves, but preferred the stalks.

Mr. A. said he felt weak and sometimes dizzy, May 6. Mrs. A. had been in good health previous to this illness.

The leaves and root of the rhubarb plant have a content of oxalic acid in the form of oxalates, the dried roots containing as high as 40 per cent. What the content in the leaves is, I do not know.

The marked exhaustion, the vomiting of bloody material, early cardiac failure, the early termination of the blood in the case of a person who had been perfectly well apparently thirty hours previous to death, led to my conclusion that death was due to poisoning from the oxalic acid contained in the leaves of the rhubarb plant.

I shall gladly answer any additional questions you may wish to ask, and would appreciate very much to hear your decision in the case.

H. J. ROBB, M.D.

COMMENT.—It seems probable that the case reported by Dr. Robb is one of oxalic acid poisoning as a result of ingesting a relatively large amount of rhubarb leaves. Both the leaves and stalks of rhubarb contain salts of oxalic acid, but the amount is greater in the leaves. A number of deaths from the use of the leaves have been reported, as far back as seventy-five years ago its toxic effects were noted. During the war the use of the leaves as a food substitute was encouraged in England; when the danger of fatal poisoning became apparent (owing to several deaths), warnings were issued against the use of the leaves. The small quantities of oxalates which occur in the stalks are seemingly ineffective in the quantities ordinarily eaten. Oxalic acid and the oxalates produce local irritation and corrosion; "in addition they produce violent stimulation and later paralysis by

depriving the tissues of their calcium through precipitation" (Solhmann, Pharmacology, 1917, p. 691). The symptoms are usually those of collapse, possibly preceded by convulsions. The nephritis produced by oxalic acid was discussed editorially in THE JOURNAL, June 10, 1917, p. 1820. The chemical antidote would be the administration of calcium.—[Ed.]

CONTROL OF BITES OF LEPTUS AUTUMNALIS, OR MOWER'S MITE

To the Editor:—Having had some experience with *Leptus autumnalis*, harvest bug, or mower's mite, last fall, I thought some one might be able to profit by a treatment for this most disagreeable insect's bite which I accidentally discovered. The mite was very prevalent in our neighborhood, and was found for some time in the hay. Men working about the barns, feeding stock, were badly bitten. The insect burrows under the skin and makes an extremely itchy area surrounding the point of entrance. Having tried all the remedies spoken of in available books, to no relief, I used kerosene to remove some very greasy ointment which had been applied with no results. Immediate relief followed the application of the kerosene. Later, I found that if a person washed the parts affected with a cloth wet in kerosene as soon as the first itching was noticed, or before the mite had penetrated the flesh deeply, the mite was killed and no further trouble resulted. Men handling the hay at chore times found it a good plan to change the clothing immediately afterward and wash the body quickly with the kerosene. This prevented the mite's burrowing. For a time these mites were so bothersome that they would incapacitate a man. The extreme itching would render sleep impossible, and the resulting scratching would not improve the condition.

NINA ALLEN GIRD, M.D., Bonsall, Calif.

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

THE USES OF YEAST

To the Editor:—Is there available information concerning the medical use of yeast? How is it taken? I should like to know whether the use of it would cause any digestive disturbance, and whether the flesh gained is normal and permanent. S. E. L., Bridgeport, Conn.

ANSWER:—Yeast is one of those remedies that have undergone alternating cycles of use and of disuse; just at present it appears again to be in its ascendancy. No doubt, the reason for these cycles has been excessive praise and merited use, followed by disappointment and consequent disuse.

Hawk and his associates (Hawk, P. B.; Knowles, E. C.; Rehnus, M. E., and Clarke, J. A.: The Use of Baker's Yeast in Diseases of the Skin and of the Gastro-Intestinal Tract, THE JOURNAL, Oct. 13, 1917, p. 1245) have recently called renewed attention to its laxative qualities. When from one-half to one cake of yeast was given three times daily before meals, it produced regular bowel movements in a number of patients suffering from constipation. That this result is not due to any vital processes in the yeast is shown by the fact that yeast killed by boiling water was employed with success. It is suggested that such yeast might be preferred for patients troubled with flatulence. Aside from the tendency of living yeast to produce diarrhea, and the possibility that it

may aggravate flatulence, no digestive disturbance has been charged against it. Aaron, in his "Diseases of the Digestive Organs," speaks favorably of its use in atonic constipation.

The much debated question whether yeast may serve as a food can be answered in the affirmative in view of such work as that of the Germans on "Nährhefe"—yeast food (Schottelins, *Deutsch. med. Wchschr.*, July 8, 1915, p. 817) and Boruttau (*ibid.*, July 29, 1915, p. 924) and of Hawk and his associates. There is no reason to assume that weight gained under its use would be more readily lost than weight gained from any other food. However, in view of its laxative action, the average individual can ingest only from 1 to 2 gm. of nitrogen a day in this form. This obviously greatly limits its value as a food. Owing to its high nucleic content, it is contraindicated in gout.

As a source of water soluble growth promoting as well as antineuritic vitamin, yeast has become thoroughly established as the result of the recent works of numerous investigators. However, as such common foods as milk, rice, wheat, oats and beans also contain such vitamin, there is little likelihood of its proving of therapeutic value on that account. In other words, yeast and other vitamin containing foods have specific growth promoting qualities only when the stunting is due to lack of vitamin. A minute amount of this substance suffices to produce maximal results. More is of no use. Hess (*Proc. Soc. Exper. Biol. & Med.*, 13:145, 1916) found yeast of no value in infantile scurvy.

The most important question in connection with yeast therapy is to what extent it is endowed with "antibiotic" power, that is, to what degree it is capable of inhibiting the growth of other organisms. That this frequently occurs in cultures in vitro is shown by the fact that yeast contamination may practically eradicate the growth of certain other organisms. That, on the other hand, this is not true for all forms of bacterial life is shown by the fact that there is definite symbiosis between yeast and lactic acid bacilli (Northrup: *Soc. Tech. Bull.*, 15, Mich. Agr. Exp. Sta., 1912).

That its "antiseptic" power is, on the whole insignificant has been shown by Palier (*Diet. & Hyg. Gaz.*, March, 1906), who found commercial yeasts commonly contaminated with numerous bacteria, the most frequent being *Bacillus coli-communis* or one of its congeners. An antagonistic action by yeast is claimed against *Staphylococcus pyogenes*, and on the strength of this, Buchholtz (Ueber Aene und eine neue erfolgreiche Behandlung derselben, *Berl. klin. Wchschr.*, Feb. 2, 1914, p. 215) employed it locally in the treatment of acne and obtained a positive but temporary effect. He believes that the effect is improved by the combination of yeast with an equal quantity of boric acid. He employed this as a dusting powder applied freely to the skin once daily, after the application of a thin layer of a boric acid salve (boric acid powder from 40 to 50, glycerin and water, of each 100) to make it stick better. In cases in which the nose was markedly involved, he also used this as a snuff. Yeast poultices have been employed with asserted great benefit in the treatment of wound infection of all kinds (Kempf, E. J.: *Ind. M. J.*, September, 1904, p. 97).

The use in leukorrhea was recommended by Hippocrates Abraham (*Mon. Geb. Sym.*, 1910) and many others report favorable results from yeast in the treatment of gonorrheal vaginitis. In various gastro-intestinal infections, yeast has been lauded by many, among others, Thierlein and Chevrety. It has been given by mouth, but most especially in high rectal enemas.

Still more from a theoretical standpoint is the reassertion of the curative value of the oral administration of yeast in various cutaneous disorders. Thus Hawk and his collaborators report cure or improvement in all of seventeen cases of acne vulgaris and eight cases of acne rosacea. They also report seventeen cases of furunculosis, in all but one of which there was cure or improvement from yeast treatment. They are unable to decide whether the result is due to the laxative action, the production of leukocytosis, or to other influences.

Yeast is probably best taken incorporated in food. Hawk and his associates found that yeast may well be incorporated in wheat biscuits, and that in this way a yeast-wheat combination of most agreeable flavor was produced; that, in fact, the biscuits with the yeast tasted better than those without it. They found by tests that in bread making as much as 20 per cent. of the flour might be replaced by dry yeast, and that thereby a loaf would be produced that was excellent in

every way and possessed of an attractive flavor. The dry yeast was prepared by desiccating compressed yeast at 105 C. in a current of air, and then milling it to produce a flour of the approximate fineness of ordinary wheat flour. They also found that yeast may be added to meat preparations, such as Hamburger steak, to the extent of 25 per cent, yielding a preparation of very satisfactory taste.

REMOVAL OF FRECKLES

To the Editor:—Is there any successful method of removing freckles? A patient of mine has some very large ones, quite unsightly. How about salicylic acid which is used in corn remedies?

HERBERT H. JOHNSON, M.D., Detroit.

ANSWER.—There is no sure cure for freckles. In time they usually disappear. But sometimes it is possible to eradicate them. Authorities differ as to the best method. Some favor diluted solutions of acids; others, alkalis. Many formulas have been suggested which are exceedingly dangerous; in fact, the death of one young woman who used a mixture recommended in a newspaper has been recorded. Among other things, mercuric chlorid, peroxid creams, horseradish, buttermilk and zinc salts have been suggested. Sutton suggests as "the most efficient remedy for the temporary removal of the eruption" a mixture of mercuric chlorid, 1 part; alcohol, 25 parts, and water 74 parts. The affected areas are rendered free from oil by the use, twice daily, of benzoin and the mercury lotion dabbed on by means of a small swab every five or six hours. As a result, a mild exfoliative dermatitis occurs and the lesions peel off. Care should be taken to avoid an acute dermatitis. If excessive irritation occurs calamine lotion or cold cream may be applied. Pusy suggests a lotion containing mercuric chlorid, 1 grain; zinc sulphate, 5 grains; tincture of benzoin, alcohol and water, each, 3 drams. He also suggests that the lesions may be treated more vigorously by the application of a paste containing from 5 to 20 per cent. of salicylic acid, alone or combined with an equal quantity of resorcin. This, of course, sets up an active inflammation and should not be trusted to a patient to use alone, but should be permitted only under the care of a physician. It may be stated that the prompt recurrence of freckles cannot be prevented ordinarily except by careful avoidance of exposure to light. This is usually too great a price to pay for relief.

SNAKE VENOMS

To the Editors:—May I ask where I can obtain information on snake venoms, especially of the "poisonous" snakes of North America? I know there has been considerable work done in Brazil along this line.

W. T. P., Kingston, N. C.

ANSWER.—The following references may be consulted:

ELIMINATION OF ANTS

To the Editor:—In *THE JOURNAL*, August 2, I noticed that Dr. Brandon, Essex, Mo., objects to the prolonged visiting of numerous ants that have been camping on him until forebearance loses its virtue. The best thing I have found is a solution of tartar emetic, sweetened. Watch for the first vanguard, put out the delectable food, and then you can be at peace.

UNIVERSITY OF PERU SCHOOL OF MEDICINE, LIMA, PERU

The complete course prescribed for medical education in Peru consists of ten years of elementary and secondary education followed by two years in the natural sciences and seven years in the study of medicine. According to the plan of the medical course, descriptive, pathologic and topographic anatomy are studied through all of the first four years, clinical surgery in the first and second, and clinical medicine in the third, fourth and fifth years. The second year includes analytic chemistry and pharmacology, followed in the third and fourth by human physiology, bacteriology and symptomatology. Nosology is given in the fourth and fifth years. In addition to the courses already named, the fifth year includes therapeutics, materia medica, clinical therapeutics, clinical otorhinolaryngology and urology. The sixth year is given to obstetrics, public health and international hygiene, ophthalmology, dermatology, syphilography, tropical diseases and clinical surgery. During the last year the student devotes his time to legal medicine and toxicology, pediatrics, nervous and mental diseases and practical exercises in legal medicine, toxicology, gynecology and clinical medicine. Practical exercises in the laboratories and botanic gardens are required especially in the first four years. Licenses are secured by passing a series of five examinations covering all of the work done in the seven years. The examinations are said to be quite severe, and the rules are very strict concerning absences from classes and practical exercises in the clinics, wards and laboratories. The total fees for examination are approximately \$500. All candidates must present a certificate of vaccination. Graduates of medical schools outside of South America are required to pass an examination in the Spanish language. By special agreement, graduates of medical schools in South America are privileged to practice medicine in any part of South America without special permission being required. Inquiries should be directed to the dean of the Faculty of Medicine, University of Lima, Peru.

MEDICAL EDUCATION AND PRACTICE IN CHINA

Under the influence of several American and other missionary boards and by the aid of such prominent American medical schools as Harvard, Yale and the University of Pennsylvania, and with the generous financial assistance of the China Medical Board, which was organized by the Rockefeller Foundation, there has been great medical progress in China in recent years, and there are twenty-six medical schools in China. Five of these at present are members

of the Association of Medical Colleges of China. Membership in this association is limited to colleges, which provide a four year medical course, and which require for admission two or more years of college work, including courses with laboratory work in physics, chemistry and biology.

Two practically new medical schools, including premedical departments, are being erected at Peking and Shanghai by the China Medical Board of the Rockefeller Foundation. These are the Peking Union Medical College and the Shanghai Medical School. The plan is to make these equal to any other medical schools in the world in buildings and equipments, as well as in hospital facilities and in educational standards.

The Rockefeller Foundation is also aiding financially other medical schools in China, particularly the Shantung University School of Medicine at Tsinan, The Hunan-Yale College of Medicine at Changsha, and the medical schools at Nankin, Canton, Soochow and elsewhere.

A strong appeal is still being made for medical missionaries. In China, with an estimated population of more than 4,000,000 people, including Manchuria and Mongolia, there are said to be at present only 2,000 scientifically trained physicians. It is stated that at the end of 1917 there were 351 foreign medical missionaries who had working with them 212 foreign physicians. During that year these physicians cared for about 130,000 hospital inpatients. Although large, these figures do not begin to touch the great needs of medical service in that country.

All civilized nations, indeed, are interested in helping to provide better medical service in China for the sake of their own people, if not for the sake of the Chinese, because China is at present the source of many of the epidemics which are liable to sweep over the entire world. It is for the medical practice of the entire world to combat disease wherever it is found by checking it at its very source.

If any physician would prefer to have a large practice regardless of the financial income involved, he would have no difficulty in securing it in China, where there is indeed great need of skilled medical service.

THE IDAHO ADMINISTRATION CONSOLIDATION LAW

By the administration consolidation law, taking effect March 31, 1919, Idaho abolished a large number of administrative boards, bureaus and other separate governmental agencies, merging them into nine departments of the state government, namely, Agriculture; Commerce and Industry; Finance; Immigration; Labor and Statistics; Law Enforcement; Public Investments; Public Welfare; Public Works, and Reclamation. Each department is headed by a commissioner, who, together with the necessary assistants in each department, is appointed by the governor. Each commissioner receives a salary of \$3,600 a year and is required to give bond in a sum of not less than \$5,000, except the commissioner of commerce and industry, whose bond is fixed at \$50,000.

All of the officers are removable at the discretion of the governor except some who, by provisions of the constitution, are appointed for a specified term. Each department maintains a central office in the state capitol, and such branch offices as are considered necessary by the governor. Each department adopts an official seal and prescribes rules for the performance of its business and the conduct of its employees. The act requires each commissioner to make a full report to the governor at the end of each year, and provides for cooperation between the departments. The Idaho administration consolidation law is similar in many respects to the Illinois civil code of 1917. The department which corresponds to the Department of Registration and Education in Illinois is that of Law Enforcement. Some of its duties are to administer the laws regulating the practice of medicine, dentistry, pharmacy, nursing, embalming, veterinary medicine, osteopathy and optometry. It also has charge of the registration of accountants, architects and surveyors, and the enforcement of the laws regarding hunting and fishing and the registration of motor vehicles.

Wherever the several laws regulating professions, trades and occupations so require, the Department of Law Enforcement is given the following powers:

To conduct examinations to ascertain the qualifications and fitness of applicants to exercise the profession, trade or occupation for which an examination is held; to pass on the qualifications of applicants for reciprocal licenses, certificates and authorities.

To prescribe rules and regulations defining, for the respective professions, trades and occupations, what shall constitute a school, college or university, or department of a university, or other institution, reputable and in good standing, and to determine their reputability and good standing, by reference to a compliance with such rules and regulations.

To establish a standard of preliminary education deemed requisite for admission to a school, college or university, and to require satisfactory proof of the enforcement of such standard by schools, colleges and universities.

To conduct hearings on proceedings to refuse licenses to persons in the respective professions, trades or occupations, and to revoke or refuse to renew such licenses.

To formulate rules and regulations when required in administering any of the professions, trades or occupations.

None of the above enumerated functions and duties shall be exercised by the department except on the action and report in writing of persons designated from time to time for that purpose by the commissioner of law enforcement.

For the medical practitioners, six reputable physicians who are graduates of reputable medical colleges and who are licensed to practice medicine and surgery in Idaho, a majority of whom shall not be representative of any one school of medicine and among whom three schools of medicine shall be represented.

The action or report in writing of a majority of the persons designated for any given trade, occupation or profession shall be sufficient authority on which the commissioner of law enforcement may act.

In making the designation of persons to act for the several professions, trades and occupations, the commissioner shall give due consideration to recommendations by members of the respective professions, trades and occupations and by organizations therein.

Whenever the commissioner is satisfied that substantial justice has not been done either in an examination or in the revocation of or refusal to renew a license, certificate or authority, he may order reexamination or rehearings by the same or other examiners.

MEDICAL EDUCATION AND LICENSURE IN COLOMBIA

The A.B. degree is a prerequisite to the study of medicine in Colombia, this degree being granted at the end of the Colombian secondary school course. The medical course covers six years of study, the first two years of which are devoted to practically the same studies as a regular two year premedical course commonly given in liberal arts colleges in the United States, except that anatomy is begun in the second year. In addition to anatomy in the third and fourth years, the student gets general and clinical pathology and surgery on the cadaver. This is followed by a year in practice of medicine, internal pathology, dermatology and ophthalmology. The last two years are given to the study in clinics of external pathology, obstetrics, gynecology, urology, hygiene, legal medicine and psychiatry. Along with the examination at the end of the fourth year the student takes a review examination on the first year's work, and likewise at the end of each succeeding year he is examined on the work both of the year just closed and also on that of the work done three years before.

The M.D. degree with license to practice is obtained by taking a clinical examination and submitting a thesis on some medical theme of public importance. Any foreign candidate for license is required to present his diploma, with photograph attached, certified by a Colombian consul or diplomatic officer in the country in which the diploma was issued. He will then pass an examination which will include clinics in a hospital.

Book Notices

LICE AND THEIR MENACE TO MAN. By Lieut. LL. Lloyd, R.A.M.C. (T.), Chief Entomologist in Northern Rhodesia. With a Chapter on Trench Fever, by Major W. Byam, R.A.M.C. (Cob). Price, \$2.75. Pp. 136, with illustrations. New York: Oxford University Press, 1919.

Recent war experiences have served to add to our knowledge of the rôle played by the insects in the transmission of disease. As a result of the Spanish-American War, we discovered that yellow fever was transmitted exclusively by mosquitos and that flies might under certain conditions be one of the chief agencies in the spread of typhoid fever. During the present war attention was focused on the menace of lice and an opportunity was offered to clarify and increase our knowledge. The author of this little book has aimed at presenting in a concise and readable manner the data accumulated in regard to various kinds of lice, their etiologic relations to various diseases and the methods found most successful for their extermination. In his avowed task of writing "for the general reader rather than for the specialist" he has succeeded quite well, and his book can be recommended to those wishing brief and yet accurate and practical information in this important public health subject. Unfortunately the manuscript seems to have been prepared too soon to include, in the chapter on trench fever, the thorough and brilliant study by the Trench Fever Commission of the Medical Research Committee, American Red Cross.

MORTALITY STATISTICS OF INSURED WAGE-EARNERS AND THEIR FAMILIES. Experience of the Metropolitan Life Insurance Company Industrial Department, 1911 to 1916, in the United States and Canada. By Louis L. Dublin, Ph.D., Statistician, with the Collaboration of Edwin W. Kopf, Assistant Statistician, and George H. Van Buren, Supervisor, Statistical Bureau. (Cloth. Pp. 397. New York: Metropolitan Life Insurance Company, 1919.

This publication covers 635,449 deaths of persons more than 1 year old occurring in the experience of the Metropolitan Life Insurance Company from 1911 to 1916. Of these deaths, 82 per cent. were of white persons and 18 per cent. of colored. The data should be of special interest in that they cover a geographic range more extensive than that of the death registration area of the United States. The tables include number and percentage of deaths, by causes, with corresponding rates, and mortality from all causes of death combined and from the principal specific causes, by color, sex and age.

Compiled with great care and covering the mortality experience of this large insurance company in practically all parts of the United States, this publication, showing the downward trend of mortality of insured wage earners from 1911 to 1916, is filled with analyses which are sure to prove valuable to public health workers.

Interesting comparisons are made between the death rates of the United States registration area for deaths and the death rates of the Metropolitan Life Insurance Company. Such comparisons by sex (age and color have been made easy for the reader by the free use of percentage tables. For the most part the death rates of the general population of the registration area do not differ greatly from the death rates of the insured policy holders; but when marked differences do exist, the writers have carefully analyzed the figures and given plausible explanations. For instance, a comparison of the mortality of wage earners and of the general population shows no marked difference in the rates below 25 years. "Beginning with the age group 25 to 34 years and thereafter there is, however, a marked excess in the rate of mortality among insured male wage earners over that among males in the general population. At these age periods, the special stresses of adult life and of employment in arduous labor make themselves felt in the mortality experience of males in an industrial life insurance company." Further analyses show that this increased mortality among male wage earners was largely due to tuberculosis of the lungs, organic diseases of the heart, pneumonia and Bright's disease.

A special chapter is devoted to tuberculosis, detailed figures being given for the various forms of this disease. Higher rates from tuberculosis of the lungs in age periods

below 20 years appear for females, but for all later age periods the rates for males exceed those for females. Of particular interest are the extremely high rates of colored persons, which in several instances are several times the rates of white persons of corresponding ages. For boys from 19 to 14 the rate for the colored (110.4) is eleven times as high as that (9.8) for white persons.

Other special chapters appear for organic diseases of the heart, pneumonia, Bright's disease, external causes of death (accident, suicide and homicide), cancer, cerebral hemorrhage and apoplexy, four principal diseases of childhood (measles, scarlet fever, whooping cough and diphtheria), diarrhea and enteritis, and diseases and conditions incidental to the maternal state, while other causes of death are treated more briefly in other chapters.

The report has a supplement showing mortality statistics of insured wage earners for the year 1917, and, finally, a brief chapter deals with standardized or corrected death rates.

The mass of data presented in this work is an important addition to American vital statistics, and the authors are certainly to be congratulated.

THIRTIETH ANNUAL REPORT OF THE NEW YORK STATE HOSPITAL COMMISSION, 1918. (Cloth. 1919.

This report constitutes a well classified collection of data pertaining to all phases of the care of nervous and mental patients in institutions. Statistical tables arranged according to psychoses and reports of scientific research, prevention work, reeducation and after-care make the report valuable not only to those engaged in similar work but also to all students of social and social-medical problems. The cost of personal services and maintenance and operation of the thirteen state hospitals in New York State for the year ending June 30, 1918, was \$9,480,808.17. The total number of inmates, June 30, 1917, was 36,138. There was adequate space for only 28,997 patients. A chart of the percentage of increase in the cost of living indicates that from 1914 to 1918 the cost of food went up 83 per cent. and the cost of fuel and light 63 per cent. The per capita cost of maintenance for the same period increased 27 per cent.

WHAT WE KNOW ABOUT CANCER. A Handbook for the Medical Profession. Prepared by a Committee of the American Society for the Control of Cancer and Published Jointly by the American Society for the Control of Cancer and the Council on Health and Public Instruction of the American Medical Association. Paper. Pp. 54. Chicago: American Medical Association, 1918.

This pamphlet has been issued under the auspices of the American Society for the Control of Cancer and the Council on Health and Publication of the American Medical Association. It presents a condensed summary of the best modern knowledge and practice in the early diagnosis and treatment of the principal forms of cancer, and of conditions which may precede its development. Those desiring a brief, up-to-date summary of this important subject will find that the pamphlet fills the purpose quite satisfactorily.

THE REDEMPTION OF THE DISABLED: A STUDY OF PROGRAMMES OF REHABILITATION FOR THE DISABLED OF WAR AND OF INDUSTRY. By Gerald Harris, Research Division, Federal Board for Vocational Education. With an Introductory Chapter by Frank Billings, Colonel, Medical Corps, United States Army; Chief of the Division of Physical Reconstruction, Office of the Surgeon-General, and a Foreword by Charles A. Prosser, Director of the Federal Board for Vocational Education. Boards. Price, \$2 net. Pp. 318, with illustrations. New York: D. Appleton & Co., 1919.

June 27, 1918, the vocational rehabilitation act became a law. It provides that every person discharged from the Army or Navy and entitled to compensation under the war risk insurance act who is in the opinion of the federal board for vocational education unable to carry on any gainful occupation, to resume his former occupation or, having entered such occupation, is unable to continue it successfully shall be furnished such a course in vocational rehabilitation as the board may provide. Mr. Harris, the head of the research division of the federal board of vocational education, tells in this book most interestingly what were the needs that led up to the passage of the law, what were the experiences of

our allies in reconstructing the human war wreckage, and what is being done to carry out the provisions of the law in the country. Especially interesting is the chapter on the pension system hitherto followed by our government, and the contrast between indiscriminate pension and economic rehabilitation. In the introduction, Col. Frank Billings, chief of the Division of Physical Reconstruction, Surgeon-General's Office, U. S. Army, tells of the organization and work of this division and the steps that have been taken for reconstruction in the Army. The book is copiously illustrated and is an exhaustive discussion of a timely subject.

Medicolegal

Duty to Provide Prompt Emergency Treatment

(Fontanella v. New York Cent. R. Co. (N. Y.), 174 N. Y. Supp. 537)

The Supreme Court of New York, Appellate Division, First Department, expresses a willingness to affirm a judgment in favor of the plaintiff, provided he is willing to reduce the verdict in his favor from \$20,000 to \$12,000, in this action that was brought, not for the original injury, but for the injury alleged to have arisen from the neglect of the defendant to provide prompt emergency treatment, by reason whereof the plaintiff's leg was necessarily amputated. The court says that while the plaintiff, a foreman for the defendant, was at work at a manhole, the cover of the manhole fell on him and broke his leg. That was between 9:30 and 9:45, or very near that time, in the morning. He was taken to an emergency hospital which the defendant had established, reaching it just after 10 o'clock. The physician whose duty it was to be there at that time had not arrived, having been delayed by the failure of his motor car. The assistant station master, who seemed to have charge, telephoned for him and found that he was not in his office, then tried to get another of the company's physicians, and finally telephoned to another hospital for an ambulance to take the man to that hospital, the assistant station master testifying that that message was sent between 10:20 and 10:30 a. m., while the surgeon connected with the other hospital, who came for the plaintiff, swore that the message was not received until after 11 o'clock. The testimony in the case further showed that, immediately on the happening of such an accident, infection sets in; that a wound with this liability to infection requires prompt, if not immediate, emergency treatment, and that the delay of only a few minutes may permit the development of that infection to such an extent as to require the amputation of the limb to save the patient's life. The evidence of the defendant's physician second sought was that he arrived at the hospital at 10:49 and gave to the plaintiff the necessary emergency treatment within a few minutes thereafter; but it seemed that the surgeon of the other hospital was there with the ambulance at nearly the same time, and immediately after the emergency treatment the plaintiff was taken to that hospital. The jury found, on what the court must deem was sufficient evidence, that the delay of approximately an hour at the emergency hospital permitted the infection so to develop that it became necessary, by reason thereof, to amputate the plaintiff's leg. It also found that the defendant had not used reasonable care in providing prompt emergency treatment. For the negligence of the first physician in failing to get to the emergency hospital the trial judge correctly charged that the defendant was not liable. The liability found by the court below was placed on the negligence of the assistant station master in charge of the emergency hospital in failing for an hour to send for an ambulance from the other hospital. A corporation must always act through its agents, and public policy would seem to require that in the providing of prompt service, when prompt service may be vital to the welfare of the patients, as well as in the providing of competent surgical and nursing attention, such an institution is under the duty to use reasonable diligence. Such a duty is not one

that can be delegated, but is one which rests primarily and always with the institution, and for the negligence of the assistant station master in failing to provide prompt emergency treatment in this case the defendant was properly held responsible.

Provisions Construed as to Physicians Testifying

(State v. Miller (Wash.), 178 Pac. R. 459)

The Supreme Court of Washington reverses a judgment of conviction of the defendant of taking indecent liberties with the person of a girl under 18 years of age, on the ground that the trial court erred in permitting a physician to testify, over objection, that he treated the defendant for gonorrhea shortly before the time of the alleged commission of the offense, which testimony was introduced by the prosecution as tending to show that the defendant had communicated that disease to the girl, there being other testimony tending to show that she had become afflicted with it about the time of the alleged commission of the offense. The court says that the state statutes provide that:

"A regular physician or surgeon shall not, without the consent of his patient, be examined in a civil action as to any information acquired in attending such patient, which was necessary to enable him to prescribe or act for the patient."—Section 1214, Rem. Code.

"The rules of evidence in civil actions, so far as practicable, shall be applied to criminal prosecutions."—Section 2152, Rem. Code.

"Witnesses competent to testify in civil cases shall be competent in criminal prosecutions, but regular physicians or surgeons, clergymen or priests, shall be protected from testifying as to confessions, or information received from any defendant, by virtue of their profession and character. . . ."—Section 2147, Rem. Code.

It seems to the court that Sections 1214 and 2147 are intended to protect two different classes of persons, and are in no wise in conflict with each other. The former protects a patient from having his physician disclose on the witness stand any information acquired in attending him as such patient, which was necessary to enable the physician to prescribe for him, while the latter has reference to the protection of the physician only; that is, so far as the patient's rights are concerned, he has the right of election under Sections 1214 and 2152 in both civil and criminal cases, and so far as the physician's rights are concerned, he has the right of election under Section 2147 in criminal cases. It seems to the court highly improbable that the legislature would accord to a patient a higher degree of protection in civil actions than in criminal actions; that is, a higher degree of protection to his right of property than to his right of liberty.

Furthermore, the court thinks that a patient's consent to his physician's testifying cannot be shown solely by the testimony of witnesses concerning the patient's previous admissions or disclosures. No decision has come to the court's attention holding that such is the law. It seems to the court that the consent must be evidenced to the trial court by some word or act of the patient at the time of the trial, so that the trial court can conclusively know, without depending on the veracity of third persons as witnesses, that the patient has waived the privilege accorded to him by the statute.

It was argued that there was nothing in the physician's testimony which disclosed any communication made by the defendant to the physician, or information acquired by the physician, when he prescribed for the defendant and treated him for the disease; and it was true that there was nothing in the testimony of the physician indicating what conversation took place between him and the defendant as his patient; but manifestly there was enough in his testimony to call for the conclusion that he acquired the information as to the defendant's being afflicted with the disease, when the defendant went to him for treatment. Wherefore the court is of the opinion that this record called for the conclusion that the physician acquired the information as to which he testified, when he treated the defendant, that such information was necessary to enable him to treat the defendant, and that the trial court erred to the defendant's prejudice in permitting the physician to testify over the objection of the defendant's counsel.

AMERICAN ORTHOPEDIC ASSOCIATION

Thirty-Third Annual Meeting, Atlantic City, N. J., June 14-17, 1919

The President, DR. HERBERT P. H. GALLOWAY,
Winnipeg, Canada, in the Chair

Treatment of Ununited Fractures Following War Injuries

DR. FREDERICK C. KIDNER, Detroit: In war fractures, recurrent sepsis was an ever present menace; even as late as eighteen months after healing of a wound, pus pockets were found in the deep tissues. Operative treatment then in delayed union was to be avoided, except as a last resort. When all external mechanical devices to overcome delayed union have been exhausted, there still remain certain true ununited fractures. These must be treated by open surgery. Such means as careful, honest, surgical observation of long standing have shown to be consistently successful should be chosen, with regard for the torn, bruised, septic tissues of the soldier, which will not stand so much surgical insult as the healthy tissues of the civilian. The easiest, simplest operations, done in the easiest, simplest way, are the best. In fractures with little loss of substance, the removal of scar tissue, and the contact of fair sized bleeding bone surfaces, will usually suffice. A catgut or other absorbable loop will steady the ends. Sometimes a simple interlocking joint, made with mallet and chisel, is necessary to secure good contact. With loss of bone substance, the bone transplant is necessary. In large bones with good nutrition, almost any type of transplant is successful. In small bones, or in large ones with much damage, the type of graft is important. When nutrition is poor, too much grooving or insult to the medullary cavity means failure. The operation of Chutro, that is, cleaning one side of the bone fragments and insertion of a wafer of periosteum and superficial cortex removed from the tibia, between the bone and the periosteum, is the method of choice in such cases. Circulation is easily established in such a transplant, and it can survive considerable sepsis. The two-stage operation will save many disappointments in operation on ununited fractures. As the first stage, all scar tissue is removed and the field explored thoroughly. The wound is then closed tightly. If no sepsis appears, one may reopen, and do the bone operation. In cases of sepsis, wide drainage is done.

DISCUSSION

DR. WINNETT ORR, Lincoln, Neb.: Nonunion would no doubt have occurred with much less frequency if treatment had included perfect immobilization and perfect position from the beginning; but, in seeing these fractures at any stage, the first thing was to try and secure immobilization, even after the opportunity might seem to have gone by. In the treatment of fractures following injury the question arises as to whether it is better to attempt to restore extremely traumatized parts in normal position, or to allow the inflammation to subside. Jones was emphatic in insisting on securing return of parts as soon as possible to normal position. If this was not done, patients presented extraordinary difficulties later on. One never could hope for good operative position later. The problem, then, is whether to establish drainage first, or secure normal position, or both together. At Savenay all that was done was to try to maintain position and immobilization and send the patients back to the United States as fully protected as possible. One point was clearly shown: that it was necessary to abandon many of the pro-

cedures and apparatus in vogue, and this principle should be carried into civil practice. It is important that a committee be appointed to revise textbooks in regard to methods of splinting. If students can be taught a simple, practical group of methods of splinting that can be applied to all fractures under all circumstances, orthopedists will have accomplished one of the most useful results to be obtained from the war experience.

DR. DEFOREST P. WILLARD, Philadelphia: Nature can do more for the bone than the physician can. Until nature proves she can do nothing more, the physician should stay out. Operative procedures should be avoided until absolutely necessary. The best help is afforded by proper fixation and immobilization. Men have been sent home to wait for operation, on account of sepsis, and have come back later with absolutely solid union. One man who lost 2 inches of bone in the tibia was sent home for six months, and came back with an absolutely solid autogenous graft of his own. It was not known where he got it. Another important point is the preoperative care of these cases. All patients should have the benefit of hydrotherapy, massage, and active and passive exercise. Tendon transplantation can be done early and the bone graft later. In regard to the interval between time of healing of the war wounds and time of operation, some men advocate going in very early. In England they do not operate for a year, but that seems a little too long. Still, it is better to be on the safe side. The best method after a severe infection with streptococcus or gas bacillus is the two-stage operation six months after injury. The Chutro graft with nearly all periosteum, to give blood supply, is the best. The conservative, slow method of operating on fractures is best.

DR. Z. B. ADAMS, Boston: It is most important to give nature a chance. Things can be done to stimulate union of bone. Jones drew attention to the fact that hammering the site of the fracture at intervals of a week would stimulate union by causing local hyperemia. In regard to metal plates, every one is agreed that treatment by metal plates is not the best way to treat delayed union. A standardized method of treatment is best in which the bones are brought into line and held there, and function of the surrounding joints and nutrition of the muscles and soft parts are maintained. Such procedures tend to limit the number of delayed nonunions.

MR. E. W. HEY-GROVES, London, England: Dr. Kidner's general remarks on this question were correct, but there is a difference in the interpretation of results. In fracture, removal of the fragments is often undertaken as a primary step. I am rather skeptical about the osteogenic power of the periosteum. If comminuted fragments are removed immediately, there is no trace found of young bone formation. If fragments are left in position from six to eight weeks, there is formation of external callus or involucrum. Comminuted fragments are full of bone cells which are poured out on the vascular portions of the periosteum. But in case of sepsis, the little bits of bone will never have the chance to do anything at all. It is not enough to introduce raw surface of bone to raw surface and then leave it. It must be tied. It is of the utmost value to put through bolts and screws of bone, ivory, metal or wire. In regard to the employment of plaster of Paris, it is undesirable after operation to put a limb in plaster of Paris and leave it for many months; but sometimes it has to be done, and muscle function has to be restored later. Some absorption or atrophy does take place at the nuts, but that is only a preliminary stage of repair in normal fractures, and repair never begins without osteoporosis, before final osteosclerosis takes place and formation of a tube. Absorption of calcium salts is not necessarily an evil. A well fitted bone may be lifted securely and kept in place by metallic suture or bone nail or screw. In the case of the femur one can take a very fine drill and make eight or ten drill holes in the axis of the bone until every one starts to bleed. In this way one can tap the vascular and cellular resources of the bone, which will help in union. Deformity cannot be prevented by use of a plaster-of-Paris cast. The most one can do is to minimize it. It is well to put on a molded splint which can be laced on, to afford protection, and by this method one is independent of very long plaster-of-Paris immobilization.

DR. E. W. RYERSON, Chicago: No single method of treatment is effective under all circumstances. If one does not wish to carry out the two-stage operation, one can test the limb by active massage and physiotherapy beforehand; if no reaction follows, and if the scar is losing its redness, one can perform the operation at one sitting. Even if there are symptoms of infection, one cannot keep the soldiers sitting in the hospital a year longer. On the other hand, there is the two-stage operation. It is difficult to persuade the soldier to submit to two operations in rapid succession, but most of them will stand for anything, provided there is hope of success. More light is needed in cases of nonunion of the femur with wide separation of the bones. It may be possible to put in Chutro grafts, which are as good as the intermedullary inlay grafts.

DR. JOEL GOLDSWORTHY, Boston: When the American forces went over there, the only thing many men knew was how to put in metal plates. The surgeons thought they obtained wonderful results. Later the staff was kept busy over here picking out the plates that the enthusiasts had put in. An order then went forth that no plates were to be put in without consultation.

DR. JOHN RIDGON, Chicago: There are two points to be considered in the question of bone grafts and plating bones: Grafts are put in to fill in a space, and plates to fix the fragments while the bones are in contact. The bone graft for filling in space meets the problem, but there is no necessity of bone grafts for fixing fragments, which can be fixed more readily by metal plates. Metallic fixation of broken bones may leave them in a pus cavity in some instances until union takes place. It is doubtful if bone inlays will unite in the presence of a large quantity of pus. Fractures can be fastened by metal attachments, and even if suppuration occurs, union will take place and the metal can then be removed. One point does not seem to be fully clear, and that is the reason for atrophy in these bones. The metal plate has been credited with all the bone atrophy. The bone atrophy which occurs in delayed union or nonunion is due more to disuse than to any other factor.

DR. CHARLES L. LOWMAN, Los Angeles: I am interested in the use of hammering instead of massage to stimulate growth of bone. There are, however, half a dozen different kinds of massage that can be used, whether light percussion or deep hammering, with treatment of parts distal to the injury.

DR. ALBERT H. FREIBERG, Cincinnati: Foreign bodies, such as plates, frequently operate as a slow cause of nonunion. Before the war, many of us had the experience of seeing fractures fail to unite until after removal of plates. The relationship of infection to nonunion is not yet perfectly understood. In my work at the Walter Reed Hospital, I found nonunion present in the presence of sequestrums. These bits of bone were left in because they had periosteal fragments and were supposed to act as osteogenic centers. It was necessary only to remove these fragments, and subsequent healing and union took place. It is not advisable to perform a plastic operation too soon. Union can be allowed to take place first.

DR. JOHN L. PORTER, Chicago: I have used a method of attaching a bone graft to these small fragments, without sacrificing bone. The small fragment is split, and a piece taken from the tibia is chiseled and driven into the fragment, this being used as a lever and dropped in, in correct position. Thus one has a bone graft with sharply pointed end, which allows of pulling the small fragment up into position.

DR. J. TORRESI ROSEN, Philadelphia: Sepsis has been considered the greatest factor in the present war, and all attention has been focused on that. The individual factor has been lost in sight. Internal secretion has a most profound influence on bone proliferation. Many of these cases of delayed or nonunion can be benefited by treatment with thyroid, or any of those glands which influence metabolism.

Experiences with Astragalectomy

DR. PEDRO CHUTRO, Buenos Aires, Argentina: The astragalus is so exactly adapted to the mortise that, except in cer-

tain fracture by rifle ball, any fracture of this bone gives rise to deformity which makes joint movement difficult. Often, when several joint elements have suffered injury, the cartilage, the bone fragments and the synovial membrane contribute to retention of pus. The liability of infection of neighboring tendon sheaths also indicates that astragalectomy should be instituted from the first, in order to drain the ankle-joint properly. This result, however, is not always accomplished. The immediate infection appears to subside, but after some weeks the foot remains swollen, and the wound bleeds easily and shows much granulation. Movement becomes impossible from pain and mechanical hindrance. The foot tends to remain swollen, the toes immobile and contracted, the sole convex, a tactile hypersensitivity persists, and the foot is entirely useless. Under these conditions amputation becomes necessary, which, in the great majority of cases, could have been avoided earlier.

In order to prevent this unpleasant train of results, certain operative technic was undertaken, as follows: The wounds of entrance and exit were cleaned, and incision was then performed in the form of an italic "S," commencing above the external malleolus, and descending along the anterior aspect of the malleolus to the line of the ankle joint, becoming then almost transverse as far as the prominence of the tendon of the tibialis anticus, and then becoming again longitudinal and descending 2 or 3 cm. Astragalectomy was then done and the foot fixed in good position. To fix the foot, a bronze wire was passed through the skin and soft parts of the inferior lip of the wound, grazing the posterior-superior border of the cuboid, and then following a recurrent path, traversing the anterior border of the external malleolus and soft parts of the other lip of the wound. The drainage tubes were placed, and the wire was twisted. Enough opening remained to allow of free drainage. If the infection had spread to the sheaths of the postero-internal tendons, débridement was done, extending to the joint. On terminating the operation, the foot was immobilized at right angles by a figure-of-eight bandage, extending from the heads of the metatarsals to the inferior fourth of the leg. Over this bandage was added a second pad of cotton, and then a new bandage, thus obtaining complete immobilization. Dressings were renewed in from fifteen to twenty days. The patient commenced to walk in the fourth or fifth week, without a crutch, leaning on the arm of a comrade, and in a few days he walked alone. Walking could be begun before complete healing of the wound. The results were very satisfactory; the shortening was negligible, and in time the patient could walk without limping.

DISCUSSION

DR. CLARENCE L. STARR, Toronto: Extensive tarsal injury makes a poorly functioning foot. Removal of the astragalus provides adequate drainage, and displacing the foot backward gives a better weight-bearing apparatus than any type of amputation. Dr. Chutro is to be congratulated on the work he has done along the lines of the tarsus.

Transference of Fibula as Adjunct to Free Bone Graft in Tibial Deficiency

DR. WILLIS C. CAMPBELL, Memphis, Tenn.: I have adopted the plan of transferring the upper extremity of the fibula as an adjunct to the bone graft. All cartilage and fibrous tissue are removed from the head of the fibula, care being taken not to injure the external popliteal or peroneal nerves. Next a cavity is made in the inferior and external aspect for the reception of the denuded head of the fibula. Heavy traction places the head of the fibula within the cavity. As the final step, the inlay graft is done in the usual manner.

Diagnosis and Preoperative Treatment of Peripheral Nerve Injuries

DR. MURRAY S. DANFORTH, Providence, R. I.: These studies were made in the Edinburgh War Hospital, in the service of Sir Harold Stiles. Diagnosis was based on history taking and routine physical examination. Single examinations were never accepted as sufficient to indicate operative measures, except possibly correction of deformities. As a rule, one examiner made all the tests. In this way possible discrepancies were noted between results of voluntary power

tests and electrical responses. In case of discrepancy, the tests were reinstituted, and the reason was ascertained. Only repeated examination could indicate the probability of anatomic loss of continuity, or that recovery would not take place. The general rule, in regard to treatment, was to wait from six weeks to two months after complete wound healing before operating, and during that time to make two or three complete examinations. The preoperative treatment consisted in improving the nutrition of the muscles, correcting any deformities and restoring flexibility of the joints in the affected extremity. If no deformities were present, the muscles were protected from stretching by proper splinting. This is important. Treatment was also given by hot soaks, whirlpool baths, massage and electrical stimulation. Restoration of flexibility of joints, especially the finger joints, was the most difficult part of preoperative treatment. Elastic traction by means of various appliances was successfully carried out. Massage and passive motion were used in association.

(To be continued)

ASSOCIATION OF AMERICAN PHYSICIANS

Thirty-Fourth Annual Meeting, held at Atlantic City, N. J.,
June 16-18, 1919

The President, DR. A. MCPHERDAN, Toronto, in the Chair

Imminent Psychology

DR. JOSEPH COLLINS, New York: Medicine, as revealed by the war, has been found lacking more in the field of neurology than in any other field. Physicians were found incompetent to examine, interpret and treat disorders of the nervous system. Neurology has not been taught adequately to medical students in this country. Psychology has been treated by pedagogists with scorn. Alleged psychiatrists have not seen the necessity of being physicians first and psychiatrists second. Eventually admissions to college will be determined by psychologic tests and not by the knowledge the applicant possesses. The choice of a profession will be determined by psychologic examination. In pedagogy, children will be classified into groups by psychologic tests, and promotions will depend on them. Potential psychoneurotics will be recognized before incapacitating symptoms arise. Feeble-mindedness will be detected.

Epidemic Encephalitis

DR. LEWELLYS F. BARKER, Baltimore: I have observed ten cases. This is not a new disease. It has been reported in connection with influenza epidemics. It corresponds to Folin's observations and with Strumpell's poli-encephalitis of adults. This is an acute or subacute nonpurulent encephalitis or encephalomyelitis. It is different from poliomyelitis and from meningitis.

DISCUSSION

DR. EMANUEL LIBMAN, New York: Dr. Straus and his co-workers found that there is a filtrable virus which is capable of producing in monkeys and rabbits lesions similar to those found in the human brain. The virus can be recovered from the inoculated animals.

DR. JOSEPH COLLINS, New York: I have seen five cases of generalized tic, torticollis and dystonia throughout the entire body.

DR. FRANK BILLINGS, Chicago: The disease existed in the epidemic of influenza of 1889 and 1890. Cases occurred during the convalescence from influenza. The worst ones were characterized by delirium and even comatose conditions, but all the patients I saw recovered.

DR. E. A. FOUSEL, Philadelphia: Dr. Barker did not speak of retention of urine, which is naturally the symptom which calls the attention of the patient to the fact that he is sick.

DR. L. F. BARKER: I have not seen retention of urine, as a primary symptom, although incontinence has been reported as a symptom.

Diagnosis of Late Syphilis of Central Nervous System

DR. CHANNING FROTHINGHAM, Boston: Since the opening of the Peter Bent Brigham Hospital, considerable attention

has been paid to the diagnosis and treatment of syphilis of the central nervous system. As a result, lumbar puncture has been performed in practically all cases in which even a suspicion of syphilis of the central nervous system was present. Two hundred and thirty-three cases were studied. The hospital diagnoses were used and the cases grouped as tabes, general paresis, syphilis of the meninges, and cerebrospinal syphilis. In each group, except that of syphilitic meningitis, there was a definite small percentage of cases, between 2 and 5 per cent, in which neither the history nor the physical examination called the attention of the examiner to the central nervous system, even after syphilis was known to be present. These cases would have been missed as cases of syphilis of the central nervous system if lumbar puncture had not been performed. Therefore, since the lumbar puncture is not dangerous, and since it may expose syphilis of the central nervous system in which physical examination has failed to do so, and since a definite diagnosis is desired early in order to institute appropriate treatment, it seems fair to demand a lumbar puncture in all cases of old syphilis before beginning treatment.

DISCUSSION

DR. JOSEPH COLLINS, New York: Lumbar puncture, as a means of diagnosis, is not comparable in any way with the ordinary symptoms. Syphilis of the central nervous system reveals itself in demonstrable ways, first by disturbance of the pupillary light reflexes, which never occurs in any other condition than syphilis of the central nervous system. Early lumbar puncture will not reveal syphilis of the central system as well as careful examination.

DR. M. J. ROSENAU, Boston: The Wassermann is a crude test, and in any series of cases the number of positive results may be dependent on the sensitiveness of the antigen used. Therefore, unless we standardize the Wassermann test, particularly with regard to the sensitiveness of the antigen, the interpretations may be incorrect.

DR. HOMER F. SWIFT, New York: I would like to call attention to the paradoxical Wassermann reaction. If one follows the reaction with the two methods—the ice box antigen and the cholesterin antigen with the warm technique—one will often find cases which will give a positive reaction with one method and a negative reaction with the other. One cannot tell which antigen is going to give a positive reaction in a given case. Results from different laboratories have often given contradictory readings because of this very fact. It is important that both methods be applied.

Findings in Three Thousand Consecutive Medical Cases with Wassermann Examinations

DR. GEORGE DOCK, St. Louis: We had Wassermann tests made in all my medical cases. No attempt was made at clinical analysis while the work was going on. We used three antigens: (1) ordinary, (2) cholesterin and (3) Noguchi. Results varied widely. In the white outpatients, positive Wassermann tests occurred in 52 per cent.; in the colored outpatients, positive Wassermann tests occurred in 48 per cent. In the tuberculosis clinic we got 23.6 per cent. positive reactions. This is in contrast to the assertion of many authorities that all chronic tuberculosis cases show positive Wassermann reactions.

DR. HIDEYO NOGUCHI, New York: I have been able to increase the sharpness of the reaction by using an acetone alcohol soluble antigen.

Chemistry of Blood in Scurvy, Especially Its Calcium Content

DR. ALFRED F. HESS, New York: Various chemical examinations of the blood were made in cases of infantile scurvy. These included the carbon dioxide content, urea, sugar, calcium and other constituents. The blood was found to be normal in all but two particulars. There was a slight increase in its acidity and a mild degree of acidosis. However, the more important finding was a decided decrease in calcium content. As the salt is approximately normal in rickets, this difference emphasizes the essential distinction between the two diseases. In spite of the low calcium content, the children did not show evidences of tetany nor did

they have convulsions, which proves that the body has a considerable factor of safety in regard to its minimum calcium requirement.

Eosinophilic Polymorphonuclear Leukemia

DR. H. Z. GIFFIN, Rochester, Minn.: The clinical characteristics noted were: splenomegaly; enlargement of superficial lymph glands, and a white count that revealed eosinophils, 73.6 per cent, and polymorphonuclear leukocytes, 24 per cent. The patient had had edema and ascites in 1911 with enlargement of the superficial lymph glands and eosinophilia. No parasites were found. He improved on medical treatment. He had a splenectomy in 1915, and apparently did well after that operation. He lived until the fall of 1918, when he died of pneumonia and empyema. Eosinophilia was constantly present. At necropsy, eosinophils were found in all hematopoietic organs.

DISCUSSION

DR. L. F. BARKER, Baltimore: We have observed one case with 71 per cent of eosinophils. I made a lumbar puncture and obtained a fluid with a large number of white cells with typical myelocytes.

DR. EMANUEL LIBMAN, New York: I saw a case in which there was edema and ascites. The fact that in Dr. Giffin's case the spleen was removed and made no difference in the condition is remarkable.

DR. A. S. WARTHIN, Ann Arbor, Mich.: Leukemic infiltration of the meninges is found in leukemia and also in chloroma.

DR. F. W. PEARBODY, Boston: Italian, aged 40, with a history of progressive weakness, a spleen which reached to the level of the umbilicus, and white count of 50,000 with 2 per cent eosinophils, lived a long time.

DR. J. A. CAPPS, Chicago: I recall a case of splenomegaly. That patient refused operation and lived eleven years. He had a white count varying from 11,000 to 21,000, and a large spleen, was in fair health, and had an eosinophilia that ran from 10 to 18 per cent, and very few myelocytes. The case was called leukemia.

Long Duration of Remission in Pernicious Anemia

DR. CHARLES G. STOCKTON, Buffalo: A case of pernicious anemia beginning in 1899 was of a serious character with gradual improvement, with interruptions, for six years. Following that there was a disappearance of symptoms, excepting the continuance of achylia gastrica. From 1917 until the beginning of 1918, the patient was apparently well, except for the continuance of achylia gastrica. In February, 1918, she had a severe relapse, the blood showing characteristic morphologic changes, although the color index was 0.8. Her condition was grave, and a transfusion of 900 cc. of blood resulted in temporary improvement. A few weeks later the patient died of lobar pneumonia. The patient had a remission of twelve years. This would seem to discredit the theory that patients sometimes recover from pernicious anemia.

Transfusion of Blood in Pernicious Anemia

DR. J. M. ANDERS, Philadelphia: According to my collective investigations, transfusion offers more for this incurable disease as a means of prolonging life than any other form of treatment up to the present day, including splenectomy, which, moreover, causes immediate death in a not inconsiderable percentage of cases. Causal treatment and the routine method of administering arsenic may be combined with transfusion of blood.

DISCUSSION

DR. FRANK BILLINGS, Chicago: One who has watched a great many of these cases must realize that there are grades and types. In 1896 I had a patient who suffered from pernicious anemia; apparently the cause was a sharp attack of influenza. He recovered so well that he worked as a night watchman for ten years. He always had a subnormal red count, and he occasionally showed nucleated cells. He had achylia gastrica during the entire time. He came into the hospital with a relapse; his blood went down to 600,000 reds, and hemoglobin 10 per cent. Another case was that of a woman who apparently recovered without transfusion and

who lived thirteen years. There must be more than one toxin in pernicious anemia. In 20 per cent there are changes in the spinal cord. In treatment, removal of the spleen or transfusion will have effect in some cases but not in others. I believe many of the cases of reported cures after splenectomy were not cases of pernicious anemia at all.

DR. JULIUS FRIEDENWALD, Baltimore: I have examined a large number of cases with reference to the gastric secretion, and I can confirm Dr. Stockton's remark that there is absence of gastric secretion. In those cases in which there is absence of gastric secretion one never finds a return of the acid again, even in the remissions.

DR. R. C. CABOT, Boston: I have seen about 800 cases. Only one patient is still alive. The present wave of enthusiasm for transfusion will fall like the red count in this disease. It is perfectly clear that you can incite a remission by transfusion more reliably than by any other method; but that the patients live any longer seems to be not yet shown; besides transfusion is not without its dangers. I have had one fatal case even after the blood was carefully grouped. The patient died within twenty-four hours after transfusion. Unfortunately, we had no postmortem.

DR. GEORGE DUCK, St. Louis: Several years ago I mentioned a patient who had lived for thirteen years. I hear every Christmas from a patient I first saw in 1906; he had neuritis as a result of Dr. Cabot's cure by Fowler's solution, but has been practically well all the time.

DR. T. B. FUTCHER, Baltimore: In 1908, I saw a woman with a characteristic picture of pernicious anemia. In 1917, she was readmitted with the first marked relapse. Unlike Dr. Stockton's patient, her blood showed features of pernicious anemia. She is still in a period of relapse.

DR. EMANUEL LIBMAN, New York: Transfusion properly carried out is without risk. If a thrombosis occurs, it is because the blood has agglutinated. You do not influence the achylia or the nervous symptoms by transfusions. I do not believe that transfusion starts a remission unless it is going to occur; but if it is going to occur, transfusion will bring it about more quickly. Though not prolonging life, we do not put the patient into much better shape for the remainder of his life.

DR. J. M. ANDERS, Philadelphia: Transfusion is not done during the remission but only when there is a progressive downward tendency. It should be done before the hemoglobin drops too low. In those cases you get good results in a large percentage of cases. I am sure my patient would not have been alive today if he had not been transfused. As to the duration of life, while it may not be true in some cases that life is prolonged, it must be true in others. The only way to know the proper time to do transfusion is by making blood examinations and examine for reticulated cells.

An Antihemolysin for the Hemolysin of Gas Bacillus

DR. W. W. FORD, Baltimore: One of the first characteristics of this hemolysin of the gas bacillus was its ability to destroy the red blood corpuscles in man. The theory that this destruction of blood was produced by the acid formed by the bacillus is not tenable. The property of the hemolytic splitting up of blood is due to an excretory product from this organism. As a rule, there is no hemoglobinuria in these cases. In pernicious anemia there is no hemoglobinuria, which may point to the fact that the destruction of the blood may be a secondary condition and not a primary one. Inoculation of animals with gas bacillus does produce hemoglobinuria, according to one observer. If destruction of the blood is an important feature of the gas bacillus, the production of a serum might have practical value.

Factors Influencing Recovery and Resolution in Pneumonia, with Special Reference to the Chemistry of the Exudate

DR. FREDERICK T. LORR, Boston: The findings suggest an explanation of recovery from pneumonia in the course of which humoral immunity is assisted by local biochemical changes. Acidosis in pneumonia may be due to partial isolation of the pneumonic lung permitting a local increase in H-ion concentration, the excess of acid formed in the exudate

gaining entrance to the circulation. Dissolution of the pneumococcus may proceed at first slowly and later more rapidly as the local acidity increases. When the H-ion concentration reaches the acid death point of the pneumococcus, crisis and recovery follow. The findings also suggest an explanation of resolution in the course of which the fibrinous exudate is locally split to a form in which it may be absorbed readily and harmlessly. With the breaking down of the cellular exudate, an enzyme-digesting protein (fibrin) in weakly alkaline and weakly acid mediums is liberated. As the acidity increases, the action of this enzyme ceases. An enzyme capable of splitting peptone to amino-acid nitrogen, also active during the proteolysis of the fibrin, is still further activated at a H-ion concentration of 6.3 or 5.2. The exudate may then be dissolved, and resolution takes place.

DISCUSSION

DR. EMANUEL LIBMAN, New York: The question of acid production by pneumococci is of great interest. In many infections there is an acid production in the body, the acid coming from the glucose. Rosenow has shown that if pneumococci are grown on the serum of a human being who is not suffering from pneumonia, there will not be acid production. There has been developed a type of pneumococci which produces acid from glycoproteins.

DR. S. S. COHEN, Philadelphia: Was the acid production in the exudate attributed to autolysis or to a biologic action of the pneumococcus?

DR. C. F. HOOVER, Cleveland: I should like to know the method of determining the hydrogen-ion concentration.

DR. FREDERICK T. LORD, Boston: In answer to Dr. Hoover's question, the H-ion concentration of the pneumonic lungs was determined by the colorimetric method after dialysis of the press juice obtained from the lungs. In one case the colorimetric determination was checked by the electrometric method. In answer to Dr. Cohen, I can only speculate as to the source of the acid which leads to an increase in the H-ion concentration of the pneumonic lung. Perhaps the most likely source is the splitting of the small amount of sugar in the blood to lactic acid. There are, however, other possible sources.

AMERICAN SOCIETY FOR CLINICAL
INVESTIGATION

Annual Meeting, held in Atlantic City, N. J., June 14, 1919

The President, DR. HENRY B. CHRISTIAN, Boston,
in the Chair

Work of the Medical Clinic

DR. HENRY A. CHRISTIAN, Boston: The present is a critical time, owing to the readjustments that necessarily must follow the disorganizing influences of war. These influences probably will work more against investigation than any other phase of our medical work. Consequently this society must use every effort to maintain the investigative spirit among its members. To accomplish this the organization of medical clinics and the relation of chiefs of clinics to their assistants is important. To bring about the best results it is important to credit to each worker his work as an independent author. I advise against the plan of joint authorship between the chief and his assistant. Freedom in investigation should be allowed to all assistants. The work of the medical clinic is to train clinicians, and consequently the problems of the medical clinic should be derived from patients and remain closely associated with patients. To bring this about it is a desirable policy to have all workers spend time in both the laboratory and the wards. A return of those preparing for clinical work to the laboratories of the fundamental sciences for a period of training is of value both to the fundamental sciences and to the clinic. Further improvement in ways and means are needed. The problem of teaching has not been solved. Suggestions and advice should be critically examined, and accepted only when their value is demonstrated. It is unfortunate that money cannot be obtained to permit of

an adequate development of clinical teaching. It is still more unfortunate that some of the sums are available only on the acceptance of fixed methods of organization. Large funds for investigation and teaching in the hands of a few may do harm or do good.

Occurrence of Anhydremia in Certain Clinical Conditions

DRS. W. McKIM MARRIOTT, St. Louis, and J. F. PERKINS, Dallas, Texas: Some infants suffering from severe diarrhea lapse into a condition simulating an intoxication. The blood of these patients is invariably concentrated. The amount of water lost from the body is sufficient to account for the rapid and great loss of weight. The desiccation explains the temperature rise. The diminished blood volume results in a fall of blood pressure, arteriolar constriction, accumulation of formed blood elements in the capillary circulation, and a greatly diminished volume flow of the blood. Renal secretion is almost at a standstill, and there is a retention of urinary elements in the blood. Acidosis results from this cause and also from the presence of the products of sub-oxidation accumulating as the result of diminished volume flow of the blood through the tissues. The administration of a sufficient amount of fluid to render the concentration of the blood normal usually results in a return toward normal conditions and a disappearance of the symptoms. In many cases it is impossible to administer sufficient fluid. The occurrence of anhydremia results in a condition which clinically and experimentally resembles very closely "wound shock." The treatment is also similar. Anhydremia results not only from diarrhea but also from any condition in which there is a diminished fluid intake or an excessive fluid loss.

DISCUSSION

DR. LEE, Boston: The condition Dr. Marriott described very closely resembles the syndrome in severe wound hemorrhage and shock. Furthermore, his observations on the blood volume correspond very closely to the observations on blood volume which we have made in soldiers. We were able to bring out one further point which Dr. Marriott did not mention in his paper: We found in general that the prognosis of our cases in soldiers depended on the fact of whether or not we were able to maintain the blood volume. In those cases in which the blood volume persistently returned to a low level despite treatment, the prognosis was bad. We estimated our blood volume by estimating the hemoglobin before and after the injection of a known amount of either saline or gum salt.

DR. OSCAR M. SCHLOSS, New York: In the course of intestinal intoxication in infants, there is a great loss of fluid through the occurrence of watery stools. Very often only small amounts of fluid are ingested by mouth. As a result, the tissues become dehydrated and there is a concentration of the blood and a consequent reduction in the blood volume. I have felt for some time that the dehydration which occurs in these cases is of great importance. Dr. Marriott has shown that the acidosis is due to the concentration of the blood and to the diminished volume flow of blood. I expressed the view that the acidosis was due to anuria, which was the result of diminished blood pressure in the kidney and also the increased osmotic pressure of the blood, due to increased protein content. The prognosis in cases of intestinal intoxication can be gaged to a considerable degree by the ability of the patients to retain water given intravenously, subcutaneously or intraperitoneally. If the injected fluid is retained, as shown by an increase of weight, recovery may occur. If the infant is unable to retain the fluid, he usually succumbs.

DR. R. T. WOODYATT, Chicago: In addition to studying the blood volume or the total water content of the blood, it is also important to study more than one kind of water in the blood. Experiments made in conjunction with Drs. W. D. Sansum and J. O. Balcar lead me to favor an idea, which is not wholly new, that in dealing with the problem of anhydremia it is necessary to recognize two fractions of blood water, namely, free water and bound water, that is, on the one hand, water comparable in a way to pure liquid water at ordinary pressures and temperatures, and, on the other hand,

water associated with proteins, sugar, salts, etc., in the form of hydrates. One of the symptoms of "intoxication" (Einkelsstein) in fever. During the course of continued intravenous injections of strongly hypertonic sugar or salt solutions in animals and men, we have seen fever develop with great regularity whenever the subject has lost by diuresis a sufficient weight of water. A loss in water amounting to only 2.5 per cent. of the body weight in normal dogs has often resulted in fever. This disappears if the water balance is restored. In this respect it is like the "manion fever" of infants which Crandell showed to be due to thirst; also to the fever which Hallerstadt described in infants undergoing changes of diet and which Peteri showed could be allayed by water alone; also to the sugar and salt fevers of Einkelsstein, which disappear when enough water is given. However, the fevers that we have observed occur during sustained injections of large quantities of hypertonic fluids into the blood stream, that is, under conditions notable for their tendency to produce hyaline plethra, and the fevers may develop even while the flow of urine is still abnormally great. The fever in these cases appears to be due not to a lowered blood volume nor to a diminution of total water in circulation, but rather to a lack of water in the right state to sustain evaporation at the rate necessary to maintain a normal body temperature. The vapor tension of the blood water appears to be lowered, but not its volume. Somewhat similar observations have been made with respect to diuresis, which may apparently cease while the blood volume is high, owing to lack of water in a state which renders it available for urine. Dr. Marriott does not, of course, say that every symptom of "intoxication" is due to diminished blood volume, and I do not so understand him. The foregoing is mentioned simply to emphasize other factors besides diminution of the blood volume which may go hand in hand with general anhydremia and which may be responsible for some of the features of the syndrome "intoxication," rather than the volume changes per se.

Observations on Blood Sugar

DR. RALPH PEMBERTON, Philadelphia: In severe cases of arthritis usually there is a greatly lowered sugar tolerance, giving very high curves as compared with the curves for normals. In groups of moderate, mild and convalescent arthritis, respectively, the sugar tolerance, with some exceptions, tends to return to normal, the curves becoming lower and flatter. In soldiers, the subject of advanced arthritis, accompanied by markedly lowered sugar tolerance, the removal of focal infection in the tonsils or teeth, when associated with relief of symptoms, was followed by a coincident and abrupt return to normal of the lowered sugar tolerance. This lowered sugar tolerance returns to normal after convalescence or cure following other lines of therapy, such as a restricted food intake and nonspecific protein injections. In cases of advanced and chronic arthritis, apparently free from demonstrable surgical foci, there may be a greatly lowered sugar tolerance giving very high curves. This suggests that the sugar tolerance may sometimes remain disturbed in long standing cases, even after the removal of apparently causative foci of infection. Patients having demonstrable surgical foci of infection do not necessarily have a lowered sugar tolerance in the absence of systemic effects. A lowered sugar tolerance is apparently specific for no disease; it parallels the course of arthritis suggestively closely; and it may return to normal abruptly after the removal of focal infection. In view of the frequency of focal infection and its effect on sugar tolerance, it is obvious that such factors should be eliminated before ascribing a lowered tolerance to any particular disease. The possible causative role of such agents in the production of the lowered tolerance characteristic of certain diseases is also suggested.

Arterial and Venous Oxygen in Pneumonia, and Its Relation to Cyanosis

DR. WILLIAM C. STADIE, New York: The blood of twenty-six bronchopneumonia patients, seven lobar pneumonia patients and five normal individuals obtained by puncture of the radial artery was studied with respect to its oxygen content and oxygen capacity by the Van Slyke gasometric

method. In the five normal cases the mean value for the arterial oxygen unsaturation, that is the percentage of hemoglobin uncombined with oxygen in the arterial blood, was 5. In the pneumonia cases the arterial oxygen unsaturation ranged from 0 to 68 per cent., and there was found a definite relation between the degree of cyanosis and the amount of arterial oxygen unsaturation. As the cyanosis increased, the arterial oxygen unsaturation increased proportionately. This points to deficient oxygen exchange in the lung. As a rule, patients show beginning cyanosis with an arterial oxygen unsaturation of 10 per cent. Only one patient with an arterial oxygen unsaturation greater than 20 per cent. recovered. In individual cases the disappearance of the cyanosis and the clinical improvement of the patient is accompanied by a fall in arterial oxygen unsaturation, and conversely, cases in which the cyanosis increased showed increasing arterial oxygen unsaturation. In only one case was there a marked diminution of the oxygen capacity. In general, venous oxygen unsaturation closely parallels the arterial oxygen unsaturation.

Activity of Heart, and Its Response to Digitalis in Pneumonia

DR. T. STUART HART, New York: In the recent epidemic of pneumonia, clinical and pathologic evidence showed that in the majority of cases death was due not to heart failure but to a general toxemia in which the heart was not primarily at fault. Digitalis studies made with standardized preparations of the drug, controlled by electrocardiographic records, indicated that in those having a normal heart at the beginning of the pneumonia the hearts showed no evidence of modification of the rate as compared with those to whom digitalis was not given. Blood pressures followed an identical course whether digitalis was given or withheld. The response of these hearts to digitalis was the same as in a similar group of hearts without pneumonia. Characteristic changes in the electrocardiographic records were obtained. Partial heart block was observed on several occasions. Two cases of mitral disease with auricular fibrillation showed a marked slowing of the heart and improvement in the circulation after the administration of digitalis. Cases with chronic cardiac valvular disease and regular heart action showed no evidence of being benefited by digitalization; in these pneumonia was fatal in the majority of instances.

DISCUSSION

DR. WILLIAM C. STADIE, Boston: The relative infrequency of cardiac failure as the cause of death in influenzal bronchopneumonia was borne out by the study of the arterial and venous oxygen content in our series of cases. The oxygen consumption, that is, the difference between the arterial oxygen content and the venous oxygen content, was not found to be increased appreciably above normal values. This would indicate that there is no slowing of the blood flow, and hence no decrease in the volume output of the heart. This was observed even in the fatal cases in which the observations were made shortly before death. In other words, cardiac failure as measured by this means did not occur in these cases.

DR. JOSEPH SALLER, Philadelphia: My experience in the camps included a large number of cases of pneumonia. At Camp Wheeler several hundred patients were receiving strict digitalis therapy; of these, four developed symptoms that, in the absence of instruments of precision, it seemed justifiable to regard as heart block. All the patients recovered promptly when the digitalis was discontinued. It is probable that in young, healthy men, auricular fibrillation, as a complication or sequel of pneumonia, is extremely rare. I failed to observe a single case of complete arrhythmia with rapid pulse during my service in the army. Among the older patients seen in civil hospitals I have observed it occasionally, on the whole very rarely. It is, apparently, the only reason for the administration of digitalis.

Renal Glycosuria

DR. SOLOMON STROUSE, Chicago: The diagnosis of renal glycosuria has been based on, first, glycosuria without hyperglycemia; second, glucose excretion almost entirely indepen-

dent of carbohydrate intake, and third, absence of diabetic symptoms. To these data should be added, I think, a fourth, and that is the absence of the development of subsequent diabetes. A few patients have been observed long enough to show that some, at least, do not develop diabetes; but, as Joslin has pointed out, a late review of all patients with this condition is advisable. Glycosuria without hyperglycemia has in the light of the more recent studies on blood sugar been found to occur in not a few cases of true diabetes mellitus. Early cases of diabetes mellitus—those, for instance, discovered in life insurance examination—not infrequently show an excretion of glucose not entirely dependent on carbohydrate intake; and in such cases the discovery of glycosuria often precedes the onset of typical diabetic symptoms. Although one can note the presence of a condition with all characteristics of renal glycosuria, it is readily seen that the clinical test of time is necessary for the final diagnosis of this condition as a clinical entity. Four patients were studied for from one year to seven years. They fulfilled all the criteria of renal glycosuria. All are in good physical condition; three are entirely free from sugar, and the fourth patient is passing an increased amount of sugar with a normal blood sugar reaction. He, too, is in perfect physical condition and with no symptoms of diabetes mellitus.

Dr. LOUIS HAMMAN, Baltimore: It is of interest to point out that the renal threshold for glucose is a variable factor and that patients with renal diabetes often show remarkable changes in their tendency to glycosuria. Several years ago, in the course of some studies on the renal threshold for glucose, I discovered two apparently healthy young adults who put out sugar in the urine, although the blood sugar did not reach 0.14 per cent. One of the two had spontaneous glycosuria after hearty meals rich in starches. From eight to twelve months later, when retested, neither patient had glycosuria, even though the blood sugar rose to 0.16 per cent.

Dr. R. T. WOOLYATT, Chicago: In connection with these discussions of the significance of the blood sugar percentage in its relationship to glycosuria, there is a point which has been brought up in previous meetings that I believe is worth emphasizing, namely, the necessity of knowing something about the volume of the blood, or, more exactly, the surface of blood exposed to cells. If the blood in the kidneys contains 0.1 per cent. of glucose, we may imagine that glucose molecules are bombarding the capillary walls at the rate of so many per second in accordance with the kinetic theory. We may assume that a certain percentage of the molecules which strike the capillary walls penetrate into them; that is, into the cells forming the capillary wall. We may also assume that the effects which glucose exerts in these calls will be proportional to the number of glucose molecules which enter them in a given period of time. It is apparent that the number which enter a given cell in any given time when the blood sugar percentage is fixed will depend on the extent of the surface which the cell presents to the bombardment of molecules. It follows that if we are to use the percentage of sugar in the blood as an index of the rate at which glucose molecules are entering the cells, we should know that the surface exposed to blood remains constant, or else know how it varies. A study of the arrangement of capillaries in a frog's foot or in the glomerulus of a kidney or other suitable location will show that an increasing blood volume is capable of inflating collapsed capillary loops and distending others, thus developing more surface for itself, and vice versa. It is therefore apparent that the surface of contact between blood and cells is a variable factor. By suitably arranged experiments, one may inject a strong glucose solution into the veins constantly at a rate just sufficient to cause a detectable glycosuria and sustain this threshold injection for hours. In a certain experiment the blood sugar percentage was found at 0.22. A large volume of extra water was then injected by vein without interrupting the glucose injection. The glycosuria continued as before. But the blood sugar percentage fell to 0.15. In this way, also, it has been possible to maintain glycosuria while the blood sugar percentage is held within normal limits. There appears to be no common agreement among different investigators as to the normal blood sugar threshold of the kidneys expressed as a percentage, and I

believe with Epstein that in interpreting blood sugar percentages there should be a correction for blood volume, or more exactly for the blood surface at the time of the blood sugar determination.

Dr. HERMAN O. MOSENTHAL, New York: I wish to endorse what Dr. Hamman said concerning the variability of the renal threshold in cases of diabetes. In one instance no sugar was excreted in the urine while the blood sugar was at a level of 0.24 per cent., whereas a few days later there was a slight glycosuria, although the glycemia had dropped to 0.18 per cent. Another point worth emphasizing in this connection is that nephritis, although it is generally supposed to raise the renal threshold to glucose, will not necessarily do this. In one case of marked nephritis the kidney was more permeable to glucose than under normal conditions, allowing sugar to escape in the urine constantly while the glucose in the blood was only 0.1 per cent.

Syphilis as a Community Problem.—As the result of much personal experience Newcomer and his associates found out that it is practicable for any well organized general hospital to establish a clinic for the treatment of syphilis without great expense to the institution and to the certain advantage of the community it serves. The fundamental questions of mortality which underlie the spread of this infection do not properly present themselves for the consideration of the physician and the hospital in connection with such a clinic. The practice of segregating the syphilis clinic from the more general work of the hospital, which has been so general, should be abandoned, as it makes the treatment appear to the patient in the light of punishment and to the hospital staff and management as a disagreeable duty. The interests of all are thus sacrificed to sentiment, and in the confusion the propaganda for better morals is not effectively advanced. Medically speaking the authors' results confirm the prevailing view that once syphilis has invaded the body it is very difficult if not impossible to eradicate the disease. Systematic treatment is, however, capable of minimizing its effects for the individual, and at the same time rendering him almost innocuous to the community. Such a clinic as this is probably more successful in securing treatment in this systematic way than is management by the private practitioner. It being assumed that such clinical facilities as those described have been made available in adequate amount, the attack on syphilis as a community problem should involve as a measure of the first importance systematic effort to secure treatment at the earliest possible moment for those infected.

Gastric Response to Pork.—For individuals with stomachs of the rapid emptying type a general average evacuation time for pork products of two and three-quarters hours was found. Subjects of the slow emptying type showed a general average of three hours and forty minutes. Pork products in general were comparatively slow to leave the stomach as would be expected from their high fat content. Roast pork was retained appreciably longer than roast beef in most instances. Pork chops required about the same period of gastric digestion as roast pork. Fried ham also required considerably longer to digest than roast beef. Minced ham showed a slight advantage over boiled ham as to evacuation time. Liver and bacon required about the same period of digestion as roast beef. Pork sausage was somewhat more easily handled than were pork chops but less readily than roast beef. Ham bologna required about the same time to digest as fried ham or as the less readily digestible beef steaks. The evacuation of bacon was found to be slow and low gastric acidities were developed. Ham sandwiches were more readily handled than most other pork products tested. "Scrapple" left the stomach more slowly than pork sausage and belongs to the less readily evacuated pork products. Pigs' feet gave variable results but appear ordinarily to be handled more easily than pork chops.

Gastric Response to Lamb.—Lamb was found to require from two to three hours (average two and one-half hours) for individuals possessing the rapid emptying type of stomach to digest and from three to four hours (average three hours and twenty minutes) for individuals with the slow emptying type of stomach. Roast lamb and lamb chops required practically the same period of gastric digestion and stewed lamb a little longer than the other two. Sheep brains left the stomach rather rapidly (two and one-half hours). On the average, roast lamb remained in the stomach a few minutes longer than roast beef, but not as long as roast pork.

Effect of Pituitary Feeding on Growth.—One hundred young rats were separated into three groups by Marius. The first group was fed on pars anterior propior of the pituitary gland, the second on pars tuberalis, and the third or control group on beef muscle. During twelve weeks of feeding the rats of the first group exhibited increased growth rate accompanied by a more rapid development of the reproductive system, evidenced by gross and microscopic hypertrophy of the organs and by the earlier birth of young. In the second (pars tuberalis fed) group there was no change in the sexual development as compared with that of the control group. The growth rate was slightly slower in the second group, owing, perhaps, to the smaller amount of meat fed. This study has not shown that any of the functions ascribed to the anterior lobe as a whole are due to the pars tuberalis.

Relation of Hypophysis to Glycogenolysis.—The results of the experiments made by Keeton and Becht favor the view that the physiologic rôle played by the hypophysis in carbohydrate metabolism does not deal with transformation of glycogen into sugar but more probably with the utilization of the sugar by the organism.

Gastric Response to Eggs.—Experiments to determine the response of the normal human stomach to eggs prepared in various ways, showed that eggs give rise to less stimulation of gastric secretion than meats and leave the stomach sooner. Raw egg white left the stomach much more rapidly than any other form of egg preparation. Raw egg yolk required much longer to leave the stomach than egg white. Hard boiled eggs required on the average a few minutes longer for gastric digestion than soft boiled eggs. Scrambled eggs required a little longer to leave the stomach than boiled eggs. Fried eggs were handled as readily as soft boiled eggs or any other type of cooked egg. Eggs scrambled or fried with a large excess of fat remained in the stomach a little longer, the difference being most marked with the rapid emptying type of individual. The belief that fried or moderately greasy foods give the stomach appreciably more trouble than others was not supported by these findings. Omelets remained in the stomach as long as scrambled eggs and longer than boiled eggs. Poached eggs, shirred eggs and soft cooked eggs were

found to be among the more readily digested forms of eggs. Eggs pickled in vinegar were digested in the same time as the hard boiled eggs from which they were prepared. Deviled eggs remain in the stomach a little longer than plain boiled eggs. Eggs with milk, or egg nog, leave the stomach a little more slowly than eggs alone, the egg albumin preventing the formation of indigestible curds in the stomach such as are likely to be formed with milk alone. Eggs with bread or French toast remained in the stomach a little longer than bread and butter alone but not longer than hard boiled eggs. Bacon and eggs were taken care of by the stomach almost as readily as fried eggs alone while possessing distinctly higher food value. Friczled beef with scrambled eggs was digested as quickly as scrambled eggs alone. Eggs and meat appear, therefore, to form a desirable combination from the standpoint of gastric digestion.

Nature of Toxic Agent in "Meat Poisoning."—The experiments reported by Greenwald were performed with a view to obtaining some information as to the nature of the substances responsible for the symptoms of "meat poisoning." The results were negative but it is believed that they help to indicate the direction which future investigation should take. The stage of decomposition of meat appears to have comparatively little to do with toxicity. Badly decomposed meat (venison, game birds) is eaten, by preference, by large numbers of people. On the other hand, meat of perfectly fresh appearance, taste and odor, but infected with a virulent strain of bacteria, may cause serious illness and death. The relatively simple substances known as ptomaines cannot be regarded as responsible for the symptoms observed. They are not nearly sufficiently toxic, particularly when given by mouth. Their existence, in any but very badly decomposed meat, is open to question. Moreover, they may be produced by the very means taken for their isolation. In these experiments no attempt was made to investigate the possible occurrence of heat stable toxins. Under ordinary conditions, it would be quite impossible to separate their effects from those produced by the ingested bacteria. "Meat poisoning" is produced by the ingestion of food that has not, as a rule, been exposed to prolonged bacterial action. Also, the filterable toxin of cholera vibrios, which will produce severe gastroenteritis when injected intraperitoneally, is harmless when given by mouth. What is true of cholera vibrios may also be true of other organisms. The rapid development of the symptoms of "meat poisoning" indicates very clearly that they are not entirely due to the action of micro-organisms within the gastro-intestinal tract. There seems to be a heat labile toxin which produces the acute immediate effects. The bacteria may or may not grow and add a further intoxication. The particular organism may be what Van Ermengen calls a "pathogenic saprophyte" such as *B. botulinus*. This organism produces a highly potent toxin but the bacilli themselves are harmless because they are incapable of growing at body temperature. With other organisms, other factors may play

a similar rôle. Greenwald suggests that further investigation is required and should take the direction of an investigation of possible heat labile toxins.

University Health Service.—The personnel of the health service established by the University of Michigan five years ago consists of five men and one woman, full time physicians, two dispensary nurses, a pharmacist, and a stenographer. The physicians were selected to do general rather than specialized work, and were given faculty standing in the department of administration, with graded rank and salaries such as existed in established lines of public health work. The financial support of the work came entirely from a general student annual fee of \$6 collected by the university at registration. A necessary part of the attention to sick students is hospitalization as part of their privileges in the health service. Such patients are sent to the hospitals operated by the medical departments of the university, where they may receive free necessary attention for a limit of sixty days. The medical service in the hospitals is given by their regular staffs and is under cooperative supervision of the health service physicians. Physicians of the health service attend students when called to their rooms. For such calls the university collects from the students \$1 for a call in daytime and \$2 for a night call, and places the money to the credit of the health service. Absolute freedom is given students in the selection of a staff physician regardless of sex. Arrangement exists by which private hospitals may be used in addition to those of the university.

Cranioplasty. Forty-two cranioplasties were performed by Primrose on thirty-eight patients. Nearly all the patients suffered from headache. As a rule, the headache was relieved completely by a successful cranioplasty. The relief of dizziness by operation was more pronounced than that of headache. In cases of deafness, noises in the ear, defective vision and aphasia, there were no observations to suggest that the operative procedure had any effect on the condition. As for hemiplegia, which was present in fifteen cases in varying degree, the condition showed progressive improvement, in every instance usually leaving a residual weakness, but in

exceptional cases clearing up entirely. It cannot be said that the closure of the defect had any remedial effect on paralysis in these cases. The value of the operation in more complicated cases, more particularly those suffering from jacksonian epilepsy, is less evident. Primrose is convinced that the value of the fascial graft is well worth considering. Where there is a cortical irritation, with much scar tissue implicating the dura mater, it is most serviceable to make a free dissection of the cicatricial tissue, removing the patch of dura mater involved and substituting a patch of fascia lata to close the rent. Where a gap exists in the cranium it should be closed. The symptoms caused by the existence of the gap and directly dependent on it will almost certainly be relieved by a successful cranioplasty.

Results of Splenectomy in Anemias.—The triumph of splenectomy, according to Mayo, is the cure of hemolytic icterus. Only patients in a terminal condition, with secondary gallstones and cirrhosis of the liver, fail to be relieved. The only patient the Mayos lost of twenty-seven splenectomized for hemolytic icterus was one operated on during an acute exacerbation.

Late Extraction of Intrathoracic Projectiles.—October, 1918, Petit de la Villeon reported about 330 and Robin ninety-two extractions of foreign bodies from the chest. There were four deaths in these combined series, a mortality of less than 1 per cent. One death was apparently due to the anesthetic, and one occurred from sepsis in a patient who had previously had an open operation on the opposite lung, and the necropsy disclosed a putrid gauze pack in the pleura. Le Conte points out that the indications for operation are: intrathoracic projectiles should be removed when the patient complains of pleurodynia, shortness of breath on slight exertion, cough or dyspnea, more or less frequent hemoptysis, and when there are signs of congestion in the lung surrounding the projectile, with slight elevation of temperature. When no symptoms referable to the projectile exist, the question of its removal should be considered with reference to the possibility of its causing future trouble. Also, fragments of projectiles should always be removed from a military patient, where their presence prevents him from reentering Class A. When the projectile lies in the mediastinum or hilum of the lung, its size and the degree of tolerance must be balanced carefully with the danger of its removal. In the average case the intervention is so simple, the extraction so easy, the recovery so prompt, and the risk so small, that due weight must be given to these things when the subject of operation is under discussion.

Thoracic Fistula and Chronic Empyema.—Patients with cavities and discharging sinuses persisting for more than two months after drainage for empyema and unsterilizable by the Carrel-Dakin method, Lilienthal says, should be examined with the vertical fluoroscope. Those with large rigid cavities and profuse discharge are proper subjects for his operation, which may be described as a major noncollapsing thoracoplasty. Small cavities, when resisting other treatment, are also suitable for this form of thoracic surgery. In fact, the procedure described by the author should, he says, be selected in the cases in which it has been heretofore customary to perform major chest collapsing operations or the Delorme-Fowler decortication.

Treatment of Empyema.—In Hartwell's opinion no form of treatment for empyema which disregards the thorough drainage of the chest cavity by a rib resection, and the gradual reexpansion of the lung by respiratory effort, meets the requirements. Other means will cure only a certain number of cases, particularly in such times as the disease occurs in abortive forms, which it has done during the past two years.

Foreign Bodies in Stomach.—One of Winslow's patients had swallowed 1,059 small steel pins and 129 hair pins, forty-nine safety pins, thirty-six pieces of wire, buttons, etc., 1,290 different pieces in all. They were removed at operation.

Strangulated and Irreducible Hernia.—The point emphasized by Risley in the report of a case is the possibility, when extensive adhesions make wide dissection of a hernia inadvisable, of placing an adherent cord and testicle within the

abdominal cavity, together with its adherent hernial sac (or bladder), doing a radical cure of the hernia and expecting a favorable, symptomless outcome.

Diagnosis and Treatment of Syphilis. L. J. Cummins, Boston.—p. 166.

Formation: A New Sign of Nerve Regeneration.—Coriat regards the formation sign of Tinel as being a valuable test for the detection of nerve regeneration. The test is very easily applied, but should be done carefully in each case, as the tingling produced by neuroma formation may lead to error. In neuroma formation or in the early stages of regeneration without neuroma formation, the formation is limited to the level of the lesion. In the neuroma formation also, where the regenerating axis cylinders are blocked and may consequently lose themselves in the surrounding tissues, the formation remains fixed at the level of the lesion. In actual regeneration of the nerve the formation progresses over the zone of the growth of the axis cylinders and can finally be detected along the partial or entire cutaneous distribution of the nerve. For a time it may involve the entire cutaneous distribution, but as regeneration becomes complete, it finally can be detected only in the extreme periphery. This formation probably is due to an increased sensitiveness of the young axis cylinders. It is best, however, not to rely on the formation sign alone. The test should be correlated carefully with the other investigations of the nerve lesion, such as protopathic and epieritic sensibility, regenerating pain points, and electrical reactions.

Childbirth. P. A. Kane, Chicago.—p. 243.

Atropin in Pneumonia.—In the treatment of influenza pneumonia Sterling has used belladonna or atropin, administered early, from $\frac{1}{150}$ to $\frac{1}{100}$ grain of atropin, or 5 to 10 drops of tincture of belladonna, to atropinize or belladonnize the system, with very good results. He has treated all influenza cases with quinin hydrobromid or dihydrobromid, in 5 grains doses, right from the start, giving three capsules night and morning with a glass of hot tea or whisky (one tablespoonful) until the temperature became normal. If the temperature was high, he gave a capsule every three hours throughout the day disregarding the deafness or cinchonism symptoms. To children quinin was administered in suppositories of cocoa butter. The dose was regulated according to age; 5 grains in one suppository, every three hours, or two suppositories night and morning. Digitalis, atropin and cocaine were also used from the start.

	gm. or c.c.	
R. Pulv. digitalis,.....	066	gr. 1
Atropinae sulphatis,....	000066 or 000099	gr. $\frac{1}{100}$ to $\frac{1}{50}$
Cocain Hydrobromid,....	0033 or 017	gr. $\frac{1}{2}$ to $\frac{1}{4}$
Strachnicae sulphatis,....	002	gr. $\frac{1}{20}$

M. S. One capsule four times a day.

To children digitalis and belladonna were administered in tincture form separately so as to be able to increase or decrease the dose as needed. Alkaline drinks were given from the start.

	gm. or c.c.	
R. Liq. potass. citratis,.....	180	36

Sig. One tablespoonful every two hours.

Sterling is convinced that this treatment lowered the mortality among his cases.

*Importance of Balanced Diet. E. S. Everhard and G. Felker, Dayton.—p. 498.

Diagnosis and Treatment of Meningitis.—The mortality in 227 instances of epidemic meningitis observed by Stone was 29.0 per cent. The mortality in fourteen instances of meningitis due to mixed infections, such as streptococcus or pneumococcus with meningococcus, was 92.8 per cent. The mortality in eighteen instances of meningitis, due to other organisms than the meningococcus, was 88.8 per cent. During the course of the epidemic 196,000 cultures were taken for carriers. The highest percentage of carriers found was 6 per cent.; the average for the entire series was 2.1 per cent. Five per cent. of the patients with meningitis had been under treatment for the carrier state at an earlier date. The spinal

fluid was cloudy in 90 per cent. of first punctures. The fluid was clear, but organisms were found in less than 1 per cent. of the recovered patients and in 2.6 per cent. of the fatal instances. The average number of intraspinal treatments in the recovered patients was eleven; the average total amount of serum each received was about 300 c.c.; the average total spinal fluid drainage was about 575 c.c. The average period of illness was fifty-two days. Among the fatal instances the average number of days under treatment before death was ten. Among 101 recovered patients, 9.3 per cent. had pectchieae while among sixty-six fatal instances, 21.2 per cent. exhibited pectchieae. Positive blood cultures were obtained in a larger percentage of patients with pectchieae, while negative blood cultures were, as a rule, obtained in those patients not manifesting pectchieae. The mortality among forty-eight patients who received combined intravenous and intraspinal therapy was 27.1 per cent.

Balanced Diet.—It is claimed by Everhard and Felker that very few people eat too much, but it is difficult to keep the fats down. Under all other circumstances the fat excess makes trouble. An excess of fat in the diet renders the urine acid to methyl red and results in bodily distress of various types. The authors suggest that high fat percentage keeps the protein and carbohydrates so low as to produce anemia and other disorders of malnutrition.

Congenital Radioulnar Synostosis, J. W. Sever, Boston—p. 203.

Radical Cure of Pelvic Deformity.—Jellett is firmly convinced that pubiotomy is a safe operation. It both enables a particular labor to be terminated satisfactorily and it cures certain degrees and types of contracted pelvis. He insists that it should be performed as long before the delivery of the patient as possible. On the other hand, he says, these are three points which are still to be decided: Should pubiotomy be performed independently of pregnancy and labor? Should it be done by the open method? Should any special steps be taken to prevent lumpy union? In Jellett's opinion it would appear as if the first two questions should be answered in the affirmative and that by so doing complications will be prevented.

Infective Hemorrhages from War Wounds.—Infective hemorrhage occurred in forty-five patients of a total of about 5,000 surgical cases that passed through the hospital in which Neuhof and St. John were stationed in one year. Many of these cases were minor ones, others did not require surgical intervention. Its incidence is, therefore, better appreciated in the statement that sixty-five of a total of 2,332 operations were undertaken for its control (2.79 per cent.). The occurrence of infective hemorrhages varied considerably with the different convalesces of wounded but was in general proportionate to the frequency of infection. The authors gained the impression that it became less common with the wider operative exposures that were practiced more and more frequently. Infective hemorrhages occurred most often if more conservative or no operative procedures were employed in the treatment of the wound. Brief histories are given of these cases.

Bone Transplants in Defects of Femur.—Davison cites cases of recent fracture of the neck of the femur without impaction, and cases of ununited fracture of the neck of the femur with diminished vitality of the capital fragment which were repaired by transplanting a segment of fibula across the union, and cases in which the head of the femur, destroyed by injury or disease, was replaced and fair function reestablished by transplantation of the head and upper part of the fibula into the upper end of the shaft of the femur in such a manner that the articular surface of the head of the fibula articulated with the acetabulum.

Recurrence of Exophthalmic Goiter.—A study of the case histories of patients suffering recurrences of exophthalmic goiter has led Sloan to believe that in many instances, if not always, the exciting cause of exophthalmic goiter and of its recurrence will be found to be of an infection, usually focal in character, which must be eradicated before cure is possible.

Occurrence of New Growths in Abdominal Wall After Laparotomy.—Two new growths in laparotomy scars, one a true desmoid and the other a fibrosarcoma, are reported by Danforth.

New Amputations of Foot.—Corlette's paper was also published in the *Medical Journal of Australia*, 1:479, 502, 526 (June 14, 21 and 28) 1919; 2:8 (July 5) 1919, and was abstracted in THE JOURNAL, Aug. 10, 1919, p. 560.

Retrospect of Otolaryngology, 1918. M. Yearsley.—p. 97.

Duodenal Stenosis.—An infant, aged 12 months, had a "convulsion" while nursing, at 10 days of age, but had no subsequent attacks. Breast feeding was continued for five months, with the addition of one bottle daily of milk and water at 4 months of age. He was then weaned. All his life he had been liable to feverish attacks, temperature from 101 to 104 F., with "green sickness," bringing up mucus and passing it per anum. These attacks had become worse. The stomach was considerably dilated and gastric peristalsis was very marked, a doubtful swelling being felt in the pyloric region. On exploration three days later the pylorus was found widely dilated, hence the obstruction was undoubtedly situated lower down, but the state of the child did not warrant further exploration or gastro-enterostomy. The boy died two weeks later at the age of 13 months. The post-mortem examination showed a stomach dilated and hypertrophied; pylorus widely dilated, admitting the first finger. The first part of the duodenum was dilated into a more or less spherical sac over 2 inches in diameter. The second part, for a distance of 1 inch, was extremely stenosed, merely admitting the passage of a probe; and the duet entered about the middle of the stenosed portion. There were no other abnormalities. The remarkable feature of the case was the prolonged duration of life with such an extreme degree of stenosis. There was no history of any attack of tetany in this case.

Catarrhal Jaundice with Influenza.—Bronson cites twelve cases of acute catarrhal jaundice in children who had been exposed to influenza but who had not had the disease in its usual form. In two other children and one adult jaundice followed a typical attack of influenza.

Influenza in Infants.—Achard claims that influenza in the infant is by no means exceptional. The forms of the disease may differ and the gravity vary. The infant does not possess any real immunity, but is merely exposed to contagion from without, the infection being chiefly contracted from the mother. Achard has seen thirty-two cases in children less than 2 years of age cared for at the Neker Hospital.

Investigation of End Results in Blood Transfusion.—Among 124 cases of transfusion of blood done by Waugh, incompatibility has been met with on three occasions. In two of these transfusion was abandoned, no ill effects persisting. The third case occurred in a patient suffering from pyemia. Injury to the donor occurred once, probably the result of the transfusion tube having been reintroduced into the donor's vein after being employed on the recipient. In closing the donor's wound, Waugh makes a point of removing one-half inch of the vein opened in case it may have suffered damage during the proceedings.

*Reamputation. A. E. Chisholm.—p. 73.
Case of Accidental Transference of Malaria Parasite in Course of Transfusion. A. S. Gubb.—p. 74.

Reamputation.—Chisholm has found the following points of practical value in reamputating: Avoid a terminal scar. It is rarely necessary, and probably rarely wise, to include muscle in the flaps. A good fibrous pad is formed between the skin with its integuments and the sawn end of bone. Reamputate clear of the disability for which reamputation is being performed, and try to make sure that no further operation will be necessary. In dealing with terminal sequestra a difference must be made between those cases in which there is little or no active sepsis present and those in which sepsis is pronounced. Reamputation should not be performed in the presence of a really actively septic wound. If the wound fills up with clot, for example, after a reactionary hemorrhage, it is well to open it right up under a general anesthetic, clear out the clot, resuture and drain in the usual way. Otherwise there will be great risk of a septic state ensuing. If the skin is scanty, and if it is important to preserve the length of the stump with a view to future function and fitting, extension may be applied by means of glue or strapping stretching from the stump to some form of wire splint. In amputation a short distance below the knee it is well to apply a posterior splint before the patient comes out of the anesthetic, for there is a great tendency for the knee to assume the flexed attitude of rest, and, if convalescence be delayed, a certain amount of contracture of the hamstrings, often difficult to overcome, may take place. If sepsis appears in a mild form after operation, fomentations or Carrel's treatment may be applied for a few days. If reamputation has to be performed in the presence of a sinus only very mildly septic, or if the muscles do not look very healthy on section, a flaying pack will be found of value, the wound being left open with a view to delayed primary or secondary suture later; or bipp may be applied, suturing the wound and providing drainage for serous oozing for a few days. In amputation below the knee the anterior edge of the tibia should be bevelled so as to prevent the sharp edge from pressing on the anterior flap. Chisholm's usual routine, before suture of the wound, has been to swab the fresh raw surface with ether, which, besides acting as an antiseptic, tends to encourage bleeding, so that small vessels which might lead to troublesome bleeding later on can be ligated at the time of operation. Ether tends also to show up unhealthy muscle by the fact that it may not react so well to the stimulus. This especially applies to avascularized damaged muscle seen soon after the infliction of the primary wound. The wound is then closed and sutured accurately. A narrow rubber dam is introduced at each end of the wound. These drains are left in for two or three days and then removed, provided no sign of infection has appeared. A thin rubber dam provides very efficient drainage and is preferred by Chisholm to tubing in most cases.

Malaria from Surgeon's Standpoint. M. White.—p. 154.

*Case of Multiple Epulides. W. W. James.—p. 156.

Initiation of Wound Shock and Its Relation to Surgical Shock.—A number of points in connection with shock are emphasized by Cowell, such as the psychic aspect of the case and the loss of circulating fluid and body heat. He agrees with other observers that during operation in such cases, or where the anatomic interference contemplated is at all extensive, the surgeon should insist on gas and oxygen anesthesia either alone or combined with regional anesthesia. During the operation a falling pressure may be counteracted by giving from 500 to 1,000 c.c. of a 6 per cent. gum solution in physiologic solution of sodium chlorid. There is no evidence of any permanent benefit following the injection of any of the numerous drugs recommended from time to time.

Jaundice Among British Troops in Italy.—The observation made by Tooth and Pringle suggest that jaundice may occur as a complication of influenza.

Effects of Artificial Pneumothorax.—Pearson's report is based on the experience gained from twenty-one patients with severe pulmonary tuberculosis whose pneumothorax he induced artificially, except in one case. The exception developed a spontaneous hydropneumothorax which Pearson converted into a controlled pneumothorax. Eleven of the twenty-one persons are alive, and all except two of these are enjoying good health and following their usual vocation. Nearly all of the ten who died had their symptoms much alleviated and their lives materially prolonged, in several instances by years, during which they enjoyed fairly good health and followed their occupations. The restoration to health and activity of most of the eleven is said to be wonderfully complete.

Cerebrospinal Fever and Atmospheric Humidity.—The studies of cerebrospinal meningitis in Egypt made by Compton add little that is new to our knowledge of the disease and its prevention, but, they afford a striking confirmation of the hypothesis previously advanced associating these outbreaks with a high degree of atmospheric humidity when the meningococcus is about. A "carrier rate" of only 1 per cent. among "noncontacts" taken at random in the Alexandria District (Egypt), and constituting therefore a fairly good "sample," as against a rate ten or even twenty times as high in England under similar circumstances, i. e., working with the same medium and technic, suggests an explanation of the comparative immunity of Egypt from the disease. With the meningococcus so little about, atmospheric humidity in Egypt gets little chance to precipitate outbreaks. Compton indicated by ventilation studies, based on the hygrometric state of the atmosphere met with indoors in occupied quarters during sleeping hours, how the greatest attention requires to be paid to ventilation as a corrective of overcrowding, in view of keeping the indoor humidity as low as possible, considering the part attributed by him to atmospheric humidity in the etiology of cerebrospinal fever.

Multiple Epulides.—In James' case every tooth of the temporary and permanent set which had erupted had associated with it an epulis. The patient was 11 years of age, and not a month breather. Very radical surgical intervention, with extraction of the teeth, controlled the condition.

*Seroibrinosis Pleurisy. P. Emile-Weil. p. 846.

Centenarians.—Laurent remarks that the alleged exceptional longevity in Bulgaria, the land of yoghurt, seems to be a question of chemistry, but the exceptional number of centenarians in California seems to be due to the natural causes of the climate, that is, the generally moderate and constant

temperature, the fertility of the soil ensuring wholesome food, and the purity of the air as the state may be said to have no manufactures while the ocean, the mountains and the vegetation are constantly purifying the air. Children live out of doors more than elsewhere, and 300 centenarians are recorded to a population of over three millions. He adds that the California centenarians are distinguished by their mental and physical vigor. Laurent describes in particular Captain Diamond whose certified record shows that he was over 118 years old at his recent death, and quotes from his book "Secret of a Longer Life and More Pleasure in Living It." Laurent adds that the more we can study the facts relating to longevity the nearer we come to the problem of life in general, and especially of what he calls infra-life, such as, for instance, the beating of a turtle's heart that is being perfused but is shut off from the vital processes otherwise. [Laurent went to California to study the centenarians and their environment.]

Heliotherapy School.—Last year Armand-Delille organized a sun bath school, like Rollier's at Leysin, for the children of repatriated tuberculous women. The school was in a hilly region in Savoie, and every pleasant day forty or fifty children, dressed only in trunks, held school out of doors. They returned to the school building for lunch, and on rainy days the children were dressed and stayed under a shelter. The classes alternated with games and gymnastic exercises, and the children were thus engaged from 8 till 4:30. By the end of a month the favorable influence was evident, and by the end of three or four months the physical transformation was complete, the suspicious glands could no longer be felt. Similar results were obtained at the Sylvabelle station (Var) with 125 repatriate children who took sun baths without clothing and all winter long. These experiences were on a scale large enough to fully confirm the necessity for heliotherapy as an integral element in outdoor schools. He does not hesitate even to declare that a course of preventive heliotherapy should form part of the hygiene for every child. It can be easily arranged on this principle of the sunlight school. Of course medical supervision is necessary, particularly as a course of sun baths may be dangerous with pulmonary tuberculosis on account of the congestive reactions which it may induce. With this reserve, preventive heliotherapy is a powerful means for fortifying the organism, and is especially effective in treatment of localized tuberculous lesions in glands.

Different Races of Pneumococci.—Nicolle and Debains reiterate that the agglutinating power of bacteria is the criterion of the race; the power of fixation of complement, on the other hand, is the criterion for the species. There may be other antigens, but those responsible for agglutination and fixation predominate. They are not peculiar to any one bacterium: Of eighty-three specimens of streptococcus tested, eighty-two agglutinated the pneumococcus I and II, and one the pneumococcus I; the cholera vibrio agglutinated both strains, while the pneumococcus II was agglutinated by meningococci, staphylococci, typhoid and dysentery bacilli, and slight agglutination for pneumococcus III was evident with some streptococci. They found further in negroes a pneumococcus IV, "such as the Americans list as purely negative," which in 8 per cent. showed average agglutination, but in 40 per cent. it displayed extremely pronounced agglutinating powers, hyperagglutinability.

Induced Pneumoserosa in Treatment of Seroibrinosis Pleurisy.—Weil has now a record of fifty cases of seroibrinosis pleurisy in which he injected air, after evacuating the effusion, until the pressure was the same as before. This ensured healing without sequelae in 82 per cent. of the cases, and the failures were in cases with pre-existing adhesions or tuberculous lesions in adjoining organs. A complete success therefore can be realized only when the diaphragm is free, but in one case the diaphragm finally regained its full play after a year of treatment, with ten interventions. In 34 per cent. healing was complete in two or three months; in a few in less than a month. In a parallel series of 86 cases simply punctured, without attempting to induce the

pneumoscercus, only 16 per cent. healed without disturbing sequelae. Of course tuberculous processes elsewhere interfere with complete healing.

Chlorin Treatment of Puerperal Vaginal Infection.—Anderodias applied Dakin's method of irrigation with neutral solution of chlorinated soda in a case of puerperal vulvovaginal thrombosis with gangrene. The outcome was favorable.

Poisoning with Castor Oil Seeds.—Baudrimont was called to a man and his wife who had taken castor oil seeds, the man eating twenty-four and the woman twelve. They ate them like nuts, and an hour later both were seized with severe vomiting and diarrhea, entailing great suffering and exhaustion, the woman screaming with cramps late into the next day, the respiration irregular and panting. Both were free from all disturbances by the fourth day, except the exhaustion. Llaenet tells of a case in which a child died after picking and eating a single seed. A number of authorities are cited by Baudrimont to confirm the danger from the toxic element in the outer covering of the seed.

- *The Diet with Diarrhea or Constipation. J. C. Roux.—p. 501.
*Physical Training of Youth. Boigei.—p. 505.
*Drug Cystitis in Typhoid. H. Roger.—p. 508.

The Diet with Diarrhea and with Constipation.—Roux reviews the diet which should be advised with acute and chronic diarrhea, with chronic diarrhea from fermentations, and with constipation, simple or with enteritis or fermentations. Analysis of his recommendations shows that, in all, the aim in the diet proposed is to modify and regulate the development of the intestinal flora. The normal digestive functions seem to require the symbiosis of certain bacteria. But we can regulate the type and the intensity of fermentations and putrefaction, and in this way make the bacteria work our will for us. As the inflamed bowel mucosa exudes an albuminous fluid, the putrefaction bacilli are favored by this, and hence restriction to water is the best way to combat diarrhea as this deprives the bacteria of this culture medium. The water should be boiled and the mouth rinsed thoroughly and often. Rice water supplies a little nourishment. A liter or a liter and a half of water at least should be given in the twenty-four hours to ward off damage from loss of fluids with acute diarrhea. The aim in feeding should be to supply carbohydrates, sugar and starch. The starch favors proliferation of acid-producing bacteria. Breakfast should be tea or cocoa with dry toast or gruel; at 10, rice water; at noon a thick gruel or *bouillon de légumes* freshly prepared, with thoroughly cooked rice or potatoes and lam, with dry toast or zwieback; at 4, cocoa made with water. At 6 the same meal as at noon. Kefir or yoghurt can soon be added, and a pudding at dinner or supper, made with milk. Later, purées of vegetables and, finally, some meat. Any excess of fats should be strictly avoided and only fresh butter used. This diet can be kept up a long while and is useful also in chronic diarrhea.

He says that with dysentery the frequent stools are only mucus and pus from the lower bowel. The patient in reality is constipated, and a milk diet, preferably with kefir, is indicated. Improvement is manifested by the appearance of

diarrheic stools, and then the above menu can be followed, as also with chronic diarrhea of the putrefaction type with putrid, dark colored stools. With chronic diarrhea of the fermentation type, the stools are light colored, and the reaction is acid. Carbohydrates must be avoided, and the use of legumes, potatoes and wheat restricted. Breakfast can consist of tea, cocoa made with water, dry toast, stewed fruit and butter. At noon, fish or meat, with rice or macaroni, cheese or pudding, stewed fruits and dry cakes. At 4 repeat the breakfast; at supper repeat the dinner. Potatoes and legumes can finally be cautiously resumed. In certain rare cases, the patients exhausted by the frequent stools, it may be necessary to restrict to water alone for a time and then give only raw meat and eggs, not allowing starchy foods until the stools have become putrid and alkaline. With children it may be best to restrict them to kefir and raw meat for a time, giving daily from 10 to 20 gm. of raw meat, to a total of 40 or 50 gm. Of course secondary diarrheas call for removal of the primary cause first.

With simple constipation he plans a dish rich in starch and fat to alternate with a cellulose dish; fruit four times a day. If there is not much toxic action, meat could be allowed at one meal. A little milk can also be taken, and three spoonfuls of bran a day may likewise prove useful. If there is much toxic action, large doses of lactose transform to acid the reaction of the cecum contents, as the *Bacillus acidophilus* gets a chance to flourish. When there is enteritis with the constipation, all the fruits and vegetables should be cooked. If there is much pain, the legumes should be dropped and the cooked fruit should be passed through a strainer. Agar will have to take the place of the laxative action of fresh vegetables. With constipation of the fermentation type, with much flatulence, all leguminous and raw vegetables must be dropped, and cooked fruits must be freshly prepared; cooked fruit standing for more than twenty-four hours is a culture medium for molds. Meat and cheese can supplement this ration, and paraffin oil gives the laxative effect. The distention from gases may kink the bowel at some point, and this should be combated.

Physical Training.—Boigei describes the special method followed at the Joinville School and the fine results obtained. Careful distinction is made, he says, between the "prepubertary," "postpubertary" and athletic exercises.

Bladder Disturbances During Hexamethylenamin Treatment of Typhoid.—Roger describes in detail a moderate case of typhoid in a man of 35 who was given hexamethylenamin by the mouth in doses of from 1.5 up to 4 and 6 gm. It did not ward off a very serious relapse, and it caused symptoms of actual cystitis. He had never had any bladder trouble before. Roger compares this painful and annoying disturbance from the medication to similar experiences on record, including Fullerton's case of medicinal cystitis in *The Journal*, Jan. 13, 1912, p. 78.

- *Pernicious Anemia with Jaundice. Chastellard and Bernard.—p. 361.
*Cancer of Colon. F. Desmarest.—p. 363.
*The Residue with Gastric Digestion. Léon Menner.—p. 364.
*The Vertigo that Restores the Hearing. P. Sollier.—p. 366.

Pernicious Anemia with Jaundice.—A previously healthy man of 51 developed pernicious anemia with jaundice, then preleukemic myeloma and finally subacute and terminal myeloid leukemia. The jaundice was not accompanied by retention of bile. In three weeks the reds dropped from 1,630,000 to 760,000, but the hemoglobin kept at 50 per cent. throughout. At the same time, the whites ran up from 2,500 to 331,000 and at last the myelocytes formed 97 per cent. The curves of reds and whites thus crossed each other.

Cancer of the Colon.—Desmarest has removed a cancer of the left colon in two cases by a left transverse supra-umbilical incision which afforded unusually ample access to the splenic angle of the colon and also to the left portion of the transverse colon and the entire descending colon. A cushion under the thorax throws the whole region into prominence, and section of the phrenocolic ligament permits easy and com-

plete mobilization of the transverse-descending angle of the colon. If the bowel is completely obstructed, the feces should be diverted through an ample incision in the cecum, suturing the mucosa to the skin.

Residues of Gastric Digestion.—Meunier has long been convinced that the usual test-meal findings do not mirror the true condition in the stomach because the gastric secretion may be more or less active without being pathologic, and because the principal function of the stomach is not secretory but motor. With abnormal conditions, four hours after a meal the stomach may still contain some of the meal, or it may all have been evacuated but the empty stomach continues secreting gastric juice. The only way to ascertain these conditions with precision is to introduce the stomach tube and have the subject lie prone, absolutely horizontal, thus utilizing the force of gravitation, instead of the usual method with the patient seated, and thus having to combat the force of gravitation. He has abandoned completely the usual test meal, and merely tells the patient to take a few stewed prunes after his last meal. The next day he eats nothing but 300 gm. of soft mashed potato, and four hours later he drinks 100 c.c. of distilled water containing 10 gm. of sugar. Then he lies prone, turning from side to side to mix the contents of the stomach, after which he sits up and the tube is introduced, and then he lies prone again. The fluid which runs out through the tube is tested for sugar, the dilution of the titrated sugar solution showing the volume of the fluid in the stomach at the time. Meunier asserts that when the residue consists merely of gastric secretion, medical measures only are called for, but residues of food, scraps of the prunes, denote some progressive trouble that calls for surgical intervention. With this method of exploration of the stomach, these surgical affections can be detected at an earlier stage than is otherwise possible, and the prospects of surgical intervention are correspondingly brighter.

Vertigo that Cures Deafness.—Sollier refers to Lermoyez' article (summarized recently, March 1, 1919, p. 685), that described certain cases of progressive deafness and malaise in which an attack of sudden vertigo is followed by restoration of the hearing. He ascribed it to a local spasm of the vessels in the internal ear, the relaxing of the spasm causing the dizziness. Sollier intentionally induces dizziness to break up the spasms or other cause of the deafness, and has been able by this means to restore the hearing in some cases of hysterical deafness, as he describes in detail. The dizziness is induced by plugging both ears deep with the forefingers and pressing repeatedly on the tragus. This induces intense dizziness so that the subject falls if the fingers are drawn suddenly out of the ears. The same effect can be realized by sending a faradic current through the skull at the tragus level. Hysterical deafness after aerial shock may be due to vascular spasm, but it is accompanied by anesthesia of the ear. The latter disappears as the hearing returns. The sudden disappearance of the deafness in these hysterical cases suggests that it is due to vascular spasm, as in Lermoyez' gony patients, and thus hysteria cannot be regarded as exclusively of psychic origin. His research confirms the physiologic conception of hysteria.

Unheated Serum in Diagnosis of Syphilis. Rubinstein points out some sources of error in the Hecht method for serodiagnosis with unheated serum. He insists that parallel tests with heated and unheated serum are indispensable.

Improved Clamp. De Martel's crusher is formed of two blades pointed at the outer end like a closed razor. They have a slight outward curve, and the clamping is done with another instrument which locks the ends of the clamp blades together. This description is illustrated, and the advantages of this simple crushing clamp are lauded as he compares it with Mayo's and Doyen's cumbersome clamps with handles and uneven crushing of the tissues, the pressure growing less toward the tip. His clamp ensures even pressure throughout, and facilitates suture.

Abscess in Lung after Gassing. A. Clerc, L. Ramond and H. Guillaumet—p. 222.

*Hemolytic Jaundice. M. Loeper—p. 223.

*Spa Treatment of Nephritis. J. Cottet—p. 225.

Carbon Dioxid Snow in Dermatoses.—Lortat-Jacob's improved method of applying carbon dioxide snow was mentioned recently in these columns, August 9, page 456. He here reports with a few illustrations the complete cure in four out of five cases of old ulcerating epithelioma of the face; four of four cases of lupus; a case of old rebellious nodular folliculitis with hypertrophy; five of five cases of keloid, including one of painful keloid, and other cases to a total of thirty-five. The results were so good that he does not wait for further experience to commend this method of treating dermatoses.

Hemolytic Jaundice.—The spleen was much enlarged in Loeper's case and the anemia was pronounced, while the red corpuscles swung periodically from 800,000 to 1,500,000 and back again, unmodified by any treatment. The hemolytic jaundice in this case presented characteristics of both the congenital and the acquired types, and the cyclic course suggests a parasitic origin. This assumption is confirmed by the benefit from arsenic in the form of arsphenamin given by the rectum. Inoculation of guinea-pigs with blood and urine gave negative results.

Mineral Waters in Treatment of Nephritis.—Cottet discusses the indications for different mineral waters when it is a question of modifying the diathesis or other disorder to which the kidney disease is secondary; also the indications when it is desired to act directly on the kidney or to ward off the evil effects of the deficient elimination of waste through the kidneys.

*Biology of Bothriocephalus. C. Janicki—p. 915.

*Cesarean Section. A. Fono—p. 919.

*Volume of Blood Corpuscles. A. Alder—p. 925.

Traumatic Hernia.—Pometta discusses hernia from the standpoint of industrial accident insurance.

Biology of the Bothriocephalus.—Janicki reports experimental research with the ligula species of bothriocephalus. The adult worm is a parasite in the intestines of water birds that eat fish, but the larvae live and grow to maturity in the fish, possibly taking two years for this, and the fish dies if the worm is not expelled. This extreme development in the first host he regards as a remarkable instance of complex adaptation of the parasite to its successive hosts.

Extraperitoneal Incision with Transperitoneal Cesarean Section.—Fono describes a method of cesarean section that he has applied in eleven cases in which infection seemed almost certain. The intervention proved a complete success in all, with no infection of the peritoneum. He packs the vagina with iodoform gauze to push the cervix up as high as possible. The abdomen is incised between the symphysis and the umbilicus, and moist sponges are packed between the abdominal wall and the uterus, shutting off the peritoneal cavity, all under local anesthesia. Then a general anesthetic is given, and the uterus wall is incised. After delivery of child and placenta, the gaping wound in the uterus is drawn up out of the abdomen and its cavity rinsed and dried and the incision is sutured in tiers. Then the parietal peritoneum is drawn up and sutured tight around the wound, about 0.5 or 1 cm. from it, thus leaving the incision outside of the peritoneum. Four or five small glass drains are left in contact with the uterus wound, as a bloody serous fluid is squeezed out. By this means any infection of the uterus wound gets no chance to spread to the peritoneum. He refrains from tamponing the uterus in clean cases as this would prevent the free escape of secretions, but in dubious

cases medicated tampons aid in checking infection. With ergot and a preparation of blood platelets, we can control hemorrhage readily without necessity for tamponing. In clean cases he sutures with silk. In future he intends in dubious cases to use catgut for the mucosa and muscle, and silk for the outer tiers. In none of the thirteen cases described in detail was there any sign of infection of the peritoneum with this extraperitoneal technic for the trans-peritoneal uterus incision.

Volume of Blood Corpuscles.—Alder describes some sources of error in the usual methods for estimating the volume of the blood corpuscles, and means to avoid them.

The Eight-Hour Day. L. Verney—p. 231.

Morphology of the Diphtheria Bacillus.—Pergola's research seems to indicate that the longer and slenderer form of the diphtheria bacillus is encountered only when conditions are particularly favorable for its growth. This explains why this type is associated with the severer forms of diphtheria. He discusses the preferable staining technic, and adds that the best means to keep the diphtheria and other bacteria alive and in good condition is by cultivating them in ordinary agar to which bouillon is successively added.

*Huge Femoral Hernia. E. Cartolari—p. 498.

Huge Femoral Hernia.—The hernia had repeatedly recurred after operative treatment, and when Cartolari operated on the woman of 48 the hernia extended to 20 cm. below the knee, spreading out in the lower part to a width of 50 cm. The operation took almost two hours, the reduction of the viscera being done very cautiously. Part of the abdominal wall had to be entirely reconstructed. He used for this four flaps from the hernial sac, arranging them one above the other, and reinforcing the whole with a flap from the fascia lata, twisted around and sutured over the whole, with an additional flap from the muscle superposed. While convalescing in bed, a hernia developed on the other side, requiring a Bassini herniotomy. The woman has worn an abdominal band during the ten months since, as Cartolari does not dare to trust too much to the weakened abdominal tissues. The case is illustrated.

*Induced Pneumoperitoneum. P. Alessandrini, p. 641.

*Earning Capacity After Trauma of the Head. E. Fossataro—p. 644.

*Injury from Common Drugs. A. Filippini—p. 651.

Da Vinci on the Organs of Sense. G. Bianconi—p. 656.

Induced Pneumoperitoneum for Radiologic Work.—Alessandrini comments on the successful introduction of oxygen or air into the peritoneal cavity, to throw the organs into relief for roentgen examination, as he has applied it in forty cases. He used an ordinary pneumothorax needle, the point made a little blunter, and his experiments on the cadaver confirmed the harmlessness of this technic. He had the patient recline, while Goetze preferred the semi-seated position in his ninety cases. In the reclining position, the abdominal walls are more relaxed and the patient is more tranquil. The needle is pushed through the rectus muscle and transverse fascia, above the umbilicus, below the liver dulness. As soon as the fascia has been traversed, he injects a little oxygen and watches the manometer to see if the tip is in the peritoneal cavity. The manometer shows the respiratory fluctuations if the tip is in the cavity, and the liver dulness disappears; the palpating hand also feels as if it were suddenly arrested as it touches the viscera, especially the cecum,

after a little oxygen has been introduced. The only mishaps encountered were that in one case the needle proved to be clogged, and in another the adhesions from chronic fibrous peritonitis had nearly obliterated the cavity.

The pressure and the amount of the oxygen must be recorded; the quantity ranged from 500 c.c. to 3 liters in his cases. It was extracted afterward in one case of large tumor as it caused dyspnea, but otherwise the gas was left to be absorbed. No effect on pulse, respiration or temperature was observed, not even with much meteorism. His experience teaches that the pressure should never be allowed to surpass that found at the beginning; this can be realized by introducing the gas slowly, as the pressure adapts itself unless large amounts are introduced too hastily. The oxygen rises, and hence the patient must assume different positions for the roentgen examinations to show up the different viscera, various modifications of the erect, horizontal and the knee-chest positions. His findings with this method of pneumoperitoneum were most instructive, and the technic worked out seems to be practical and harmless. The contrast meal throws no light on anything outside of the digestive tract, but oxygen exaggerates the contrasts with all the viscera.

Earning Capacity After Trauma of the Head. Fossataro gives the clinical history of seventeen patients followed for nine up to fourteen years after an accident injuring the head. The outcome differed so widely in the various cases that it is impossible to foretell what the result will be after such accidents. Some had their earning capacity reduced by 50 per cent., others only by 15 or 20 per cent., although the trauma seemed graver in some in this latter group. Injury of the occipital region seemed more serious, even when there was no fracture. One man died from the effects of the trauma, fourteen years later, although he had shown great improvement during the last few months. The seventeen cases are described in detail, and Fossataro reiterates the necessity for being extremely guarded in pronouncing the prognosis after injury of the head.

*Operative Treatment of Causalgia. R. Mosti, p. 809.

Present Status of Treatment of Epithelioma Guttur. G. Dragotti, p. 812.

Health Insurance in Different Countries. L. Verney—p. 817.

Causalgia.—Mosti reports a case of extremely severe causalgia in which the projectile seemed to have injured merely the artery alone. Resection of the segment of the artery involved, with its corresponding sheath, cured the agonizing pain at one stroke. This does not harmonize with the prevailing conception that causalgia is due to an ascending neuritis of a trunk nerve, or neuritis of the peripheral sympathetic. In his case the humeral artery was completely obstructed by thrombosis, and the lesion involved the artery alone. There was no injury of the nerve, but the sheath of the artery was involved in the lesion. The case suggests that injury of an artery may be the primal cause of causalgia. Even when the sheath alone seems injured, the artery may have suffered. Tenon insists on removing a segment of the sheath of both artery and vein in this "peripheral sympathetomy" as Leriche calls it. Boldo recently reported eight cases of causalgia cured by "electrolytic dearteriation" of the nerve according to Negro's technic. The causalgia involved the sciatic in three cases, the median or the ulnar in two and in three both these nerves. In some of his cases the artery had been injured as well as the nerve. He also is convinced that the intervention should include the sheath of both vein and artery, but simple excision of the sheath of the artery has seemed to answer all purposes since Leriche introduced this "peripheral sympathetomy" in 1916.

Echinococcus Disease of the Lung. A. Fagnoli—p. 498.

Reflex Contracture and Paralysis. G. Chavigny—p. 502; Ed. P. Boveri—p. 502.

Present Status of Spontaneous Arthritis. G. Molinari—p. 504.

Primary Echinococcus Disease of the Lung. Fagnoli emphasizes that in the case described there was nothing to

distinguish the true nature of the process until roscoposcopy cleared up the diagnosis at once, showing the round cysts in the lung. The seroreaction was not positive and there was no eosinophilia until after exploratory puncture. Soon after the latter there were violent paroxysms of coughing, with blood-streaked expectoration, fever and rapid pulse, but the third day order was restored.

Reflex Paralysis and Contracture.—Chavigny reiterates that even long established hysterical paralysis and contracture may yield finally to the proper measures, as in a case of contracted hand described in which the *main ficile* of four years' standing relaxed at once as the fingers were passively scissored under the faradic current. Boveri relates that in many cases sent to his service labeled reflex paralysis or reflex contracture, some lesion in the joint or tendon was finally discovered. An excrescence on the bone or a foreign body may finally reveal an organic cause for what is assumed to be a purely functional or factitious disorder.

February, 1919, 9, No. 2

*Sclerotic of Splanchnic Vessels. A. Austregesilo—p. 85.

*Treatment of Vagotony and Sympathicotony. H. Noronha—p. 92.

*Improved Urosecretory Constant. J. M. da Fonseca—p. 100.

Sexuality and Psychoneuroses.—Austregesilo declares that his long years of experience as neurologist and psychiatrist have convinced him that sexuality is an important factor in most if not all cases of psychoses. In every form of dementia, toxic psychoses, psychoneuroses, imbecility and idiocy he has detected anomalies in the genital sphere in almost every case, if not in all. Erotic elements are evident in the delirious ideas. The history of mankind, he says, is a record of war and religious mysticism, and both of these are expressions of the sexual instinct, the manifestation of the strength of the male and of the self-sacrificing devotion of unselfish love. The problem of sexuality has been studied by poets, novelists and artists of all ages, but scientists have been very timid and reserved until Freud's pioneer work. In conclusion, Austregesilo offers the aphorism that those living normal sexual lives do not suffer from their nervous system.

Treatment of Vagotony and Sympathicotony.—Noronha claims that the main thing in treatment of either condition is to aim to restore tone to the unstable nervous system as a whole; atropin can then be given for vagotony and epinephrin or sympathicotony, but the doses should be small and cautiously given.

Improved Urosecretory Constant.—Da Fonseca has modified Ambard's formula, to eliminate certain sources of error. The formula he advocates is based on the azotemia per liter; the actual and the normal amount of urine in the twenty-four hours, and the urea per liter of urine. The subject is prepared for the test the same as for the Ambard formula. The functional capacity of the kidneys is estimated by the proportion between the urea in the blood and in the urine and by the volume of urine secreted. The formula is thus as follows: $\frac{\text{constant of coefficient equals the urea percentage in the blood divided by the urea percentage in the urine, multiplied by the amount obtained by dividing the actual volume of urine by the normal volume of urine. The standard for the normal amount of urine is calculated for each subject by dividing the weight in kilograms the excess in centimeters over 1.60 m. by 1 meter. The figure thus obtained is multiplied by 10. For a woman he subtracts 10 per cent from the figure thus obtained. The calculation thus would be as follows: For a man weighing 70 kg. and 170 meters tall $70 \times 10 = 700$. For a woman weighing and measuring the same would be identical except for subtracting 10 per cent from the result. The constant normal coefficient obtained with this formula and simple formula ranges from 0.015 to 0.018 and is, therefore, remarkably instructive when compared with Ambard's constant and the clinical course. The simplicity of the formula is an advantage. When the coefficient runs up to 0.02, 0.03 or 0.04, the kidneys are woefully deficient, less than 0.009 or 0.0095 indicates any functional capacity left. Less than 0.003 also denotes severe kidney insufficiency, which is observed in nephritis and the drop type.$

*Sclerosis of Splanchnic Vessels. S. Martínez Gómez—p. 257.

*Phlegmon in Ischio-rectal Fossa. F. Martínez Suárez—p. 267.

*Cancer of the Pylorus. N. Mendizábal—p. 279.

Sclerosis of Splanchnic Vessels.—The sclerosis in Gómez' three cases induced attacks like those of angina pectoris in the abdomen. Under repose and medical measures the condition improved, but it grew worse again as active life was resumed. The pain was always in the upper abdomen and never spread to the thorax, neck or arms. It came on almost suddenly, after the principal meal, and was brought on by exercise. It yielded rapidly to repose and did not return at any other time of the day in two of the patients. The third had the pain develop after each meal and also during the night, but it stopped when he stood up. In this case aerophagia evidently cooperated in the clinical picture. Such patients should lead a tranquil life, avoiding excitement and stimulants and overloading the stomach. The heart should be supervised.

Ischio-rectal Phlegmon.—Suárez relates that periproctitis and peritonitis followed the ischio-rectal phlegmon, with death the eighth day. The patient was a previously healthy man of 56.

*Colorimeter for Measuring Doses of Vaccines. A. M. de Miranda and C. de Miranda—p. 127.

*Syphilis in Brazil. O. Clark—p. 127. Cont'd in No. 2, p. 166.

Dosage of Vaccines.—Da Cunha and de Miranda determine the strength of a bacterial vaccine by the opacity of the emulsion. They give the formulas to use with the colorimeter for the purpose, as worked out by comparative tests with Sabouraud's weighing method.

Syphilis in Brazil.—Clark relates that de Mendonça obtained a positive Wassermann reaction in 50 per cent of the thousands of patients that passed through his surgical service at the Hospital de Beneficência Portuguesa during a certain period, but this hospital is for the Portuguese colony and the disease may have been acquired abroad. Clark tells further of a group of 14 medical students of the best social standing, men who knew the dangers of venereal disease, but recent examination twelve years later shows signs of syphilis in 9, including several with grave visceral lesions. Clark's article was read at the First South American Congress of Dermatology and Syphilography at Rio last fall, and the data he presented confirm the enormous prevalence of syphilis in Brazil. The vital statistics do not show this as the underlying syphilis may have been overlooked or, as in one case he knows of, the man of 30 committed suicide because he had contracted syphilis. He cites examples further of tuberculosis developing in a healed syphilitic cavity in the base of the left lung. He adds that syphilis seems to be even more prevalent in northern Brazil. A large proportion of the heads of families in northern Brazil die at about the age of 40, victims of cardiovascular, nervous or visceral syphilitic lesions. From his three years in the hospitals of Europe and New York and eight years in a Rio hospital, he thinks Brazil far surpasses those other countries in the prevalence of syphilis. General paralysis, which is said to be rare in tropical countries, is becoming more frequent as physicians are growing more skillful in diagnosing it.

Clark adds that there can be no doubt that syphilis in Brazil runs a mild course, as a rule, notwithstanding the inadequate treatment. The proportion of tertiary manifestations is very small in comparison to the total number of syphilitics. The race as a whole is the strongest he knows of, which contradicts the assumption that syphilis is an important factor in the degeneration of a race. He describes the findings in fifty cadavers with grave visceral lesions, supplementing this with the clinical history of 6 cases of syphilitic liver disease, with recovery in some; 2 with acute yellow atrophy of the liver subsiding under treatment; and one case of primary enlargement of the spleen with sec-

dary anemia, negative Wassermann reaction and anamnesis, and the blood picture normal. The spleen measured 35 cm. but returned to normal size under mercury. A few months later a gumma developed in the abdominal wall, and at this time the Wassermann reaction was positive. Later he suffered from intense gastralgia which subsided likewise under mercury. In one young man of 18 the splenomegaly seemed to be traceable to inherited syphilis. It subsided only partially under specific treatment; the liver was enlarged also and there was some ascites. Splenectomy seems the only relief in such cases.

*Secondary Dyspepsia. L. Razetti.—p. 91.

Oxytic Action of Quinin. R. Medina Jiménez.—p. 96.

Secondary Dyspepsia.—Razetti refers mainly to dyspepsia secondary to appendicitis, describing several typical cases. The patients had been treated and dragged for years until the casual discovery of tenderness at McBurney's point first attracted attention to the appendix. One woman applied to him for an operation on the stomach as she was so weary of taking medicines for her hypochlorhydric dyspepsia of many years' standing. In this case palpation revealed an ovarian cyst. In other cases the McBurney point gave the clue or the tender gallbladder—in all, the removal of the ovary, appendix or gallbladder seemed to cure at one stroke the chronic dyspepsia. All patients with digestive disturbance not explainable by other means should have the appendix examined. If this can be excupulated, all the other pelvic and abdominal organs should be interrogated in turn, remembering that a chronic inflammatory process often develops without any acute warning of its existence. Lobo corroborated his statements, saying that the appendix is undoubtedly responsible for 50 per cent. of the cases of dyspepsia, but Ruiz declared that these speakers overlooked the importance of syphilis as a cause of dyspepsia. From simple hypersecretion to Dieulafoy's ulceration, all forms of dyspepsia may yield to treatment of the underlying syphilis.

*Typhus in America. R. Kraus.—p. 131.

Hookworm in Coal Mines of Southern Chile. J. Née.—p. 148.

Case of Cerebral Syphilis. H. I. Plaza.—p. 157.

Typhus in America.—This article has already been briefly mentioned in these columns, when it appeared elsewhere. Kraus emphasizes that neither by cultures nor by microscopic or histologic findings is the differential diagnosis of typhus possible. Even the process of necrosis in the walls of the small arteries, and cellular infiltration around the ramifications, to which E. Fránkel called attention as pathognomonic of typhus, were found in three influenza cases at the Hospital Muñiz at Buenos Aires. Monkeys react with fever to intraperitoneal injection of typhus blood. They are more sensitive than guinea-pigs, but the monkeys of the Americas are less sensitive than those of the Old World. Nicolle has reported that the micrococcus of Malta or undulant fever is agglutinated with typhus serum more effectively than with any disease except Malta fever itself. The sero-reaction with the *Bacillus proteus* isolated from the urine of typhus patients, especially the strain known as X 19, is said to give a characteristic agglutination in 90 per cent. of cases. An alcoholic preparation gave more responses than the live cultures in Kraus' tests, and the alcoholic preparation is said to keep for two years. Sordelli emulsifies two agar tube plant cultures with 2 c.c. of physiologic saline and adds

alcohol to four times the volume, and after setting aside for an hour, he decants the alcohol. The sediment is then emulsified with physiologic saline, the volume equal to that of the alcohol. He then adds 0.5 per cent. phenol, and after waiting twenty-four hours, adds 8 drops to the serum to be tested. The directions with a European preparation are that each 0.5 c.c. of diluted serum calls for 0.1 c.c. (4 drops) of the alcoholic preparation.

*Plastic Surgery of the Cheek. R. de Mata.—p. 129.

*Coexistence of Gonorrheal Tuberculosis and Uterine Fibromioma.

—R. R. de Bengoa.—p. 135.

*Septic Phlebitis. Inigo.—p. 143.

Surgery of the Cheek for Epithelioma.—De Mata's incision was carried from the ear to the middle of the chin but just below the jaw all the way except at the point of the chin, where it ran up to the lip. The diseased glands in the neck were then excised, and then the incision was carried around the edge of both lips to the median line. This allowed the entire skin of the cheek to be turned back to the orbit and nose. The tissues beneath were then turned back toward the ear, leaving the mucosa lining of the mouth intact except the gap where the epithelioma was cut out. This was repaired with mucosa from the lips, and the severed Steno's duct was reimplanted in the mucosa. The linear scar left is in the shadow of the jaw and is scarcely perceptible, especially as the man has grown a beard since. Healing was prompt and perfect, and the mouth could soon be normally opened.

Fibromatosis of the Uterus Plus Tuberculous Ascites.—De Bengoa lists the case described as *un caso clínico de quimocelias antagónicas* on account of the coincidence of the tuberculous lesions and ascites with the fibromatosis of the internal genital organs and peritoneum. After resection he refrained from draining and applied heliotherapy, with excellent results.

Septic Phlebitis.—Inigo noted a rise in temperature and acceleration of the pulse as the only signs in certain cases of insidious septic phlebitis. The fever is not high but occurs spasmodically and may be of brief duration, preceded by a slight chill or at least by a feeling of chilliness and malaise, when there may be nothing to suggest inflammation or supuration in the wound. Necropsy in some cases of this kind cleared up the diagnosis for the first time. One of the typical cases described was that of a woman who had had a large left ovarian cyst removed and seemed to be smoothly convalescing, when she developed periods of malaise with slight chills, slight rise in temperature and pulse of 90 to 120, these brief periods alternating with euphoria. The laparotomy wound healed perfectly, but the patient said she felt as if she had hemorrhoids only they were higher up than they should be. No hemorrhoids could be discovered. The recurring slight and brief fever was ascribed to absorption of cyst contents, as some had been spilled at the laparotomy, and the woman was to have left the hospital at the end of the third week, when she died suddenly the night before. Necropsy revealed embolism from septic phlebitis. There had been no edema at any time, no phlegmasia alba dolens, but if the blood had been examined when the woman complained of the "high hemorrhoids," it might have given the clue. At least, it would have shown the necessity for keeping the woman in bed. Septic phlebitis was responsible for 60 per cent. of the mortality with war wounds of the chest, according to Borrows, and in an even larger proportion with wounds in the limbs.

- *Case of Adiposogenital Dystrophy.—J. Destefano, p. 535.
 Proposed Reform of Medical Curriculum.—N. V. Gizzo, p. 539.
 Hemorrhagic Purpura of Syphilitic Origin.—L. I. Rabuffetti, p. 541.
 Ossifying Myositis.—R. A. Rivarola, p. 544.
 Hypoparathyroidism.—Id.—p. 545.

Adiposogenital Dystrophy.—Destefano says that the retrospective diagnosis in the man of 50 is that the inadequately treated attack of cerebral syphilis fourteen years before had modified the pituitary body and adjoining sugar center so that symptoms of perverted functioning in each became apparent. Obesity developed, with loss of genital functions, loss of all the hair on body and limbs, except at the pubis and axillae, and the urine finally showed up to 1594 gm. of sugar. The pituitary body was seen to be smaller than usual, evidently the seat of sclerosis.

Purpura of Syphilitic Origin.—Rabuffetti argues that the syphilitic origin in the case of severe hemorrhagic purpura described is established by the complete cure under treatment for the syphilis alone. The patient was a painter of 27, but calcium chloride and similar measures for the hemorrhagic purpura and complicating hydrarthroses failed to display the least benefit. Under mercury and arsenphenamin, recovery was soon complete. The tolerance for arsenphenamin was remarkable. Two or three months later he complained anew of pains in bones and joints at night, and treatment was resumed.

Ossifying Myositis.—The case described by Rivarola has been published before (Centeno, 1915), but the course since has shown the necessity for exceptional hygiene in this disease. The child keeps in good condition in the hospital, but when the parents take the boy home the condition develops acute aggravation. The child presents congenital deformity of the toes, the arrested development here confirming the general assumption of the embryonal origin of the disease. Rivarola adds in conclusion that congenital malformation, arrested development, of fingers or toes should warn of the possibility of the child's being a candidate for ossifying myositis later. The hygiene and development should be supervised with special care in consequence.

- *Psychoanalysis.—J. Borst, p. 1650.
 Calcium Content of the Blood in Children.—S. B. de A. Robles—p. 1663.
 Old Person.—I. Heymans, p. 1671.
 Enteric, Enteropneustic or Enteroplathic Influenza?—S. J. Van Wijk—p. 1673.

Psychoanalysis. This is an address delivered by Borst at a conference of railroad physicians, as he thinks that their special field of practice can derive great benefit from Freud's pioneer work on the origin and cure of neuroses. He describes a number of striking incidents from his own experience, and emphasizes the difference between the results obtained with the older methods of treatment and those now realized by exploring and cleaning out the subconscious elements. Thirty years ago, for instance, he tried to cure a tendency to somnambulism with hypnosis, but the success was only transient and the somnambulism kept up. Now, in such a case, he investigates the circumstances of the first appearance of the tendency to somnambulism. This gives insight into the subconscious, and as this is brought into the light and discussed, a complete and permanent cure is realized. This we owe to Freud, he says, but Borst does not follow him to the extreme of accepting a sexual element in every case. It is this feature of psychoanalysis which has attracted lay attention to it in an undesirable degree. In some of the cases Borst describes, the marriage of a sister below her rank, discovery of cheating by an employee, or a severe fright was the cause of the nervous diarrhoea, hysterical instability, or attacks of depression, anorexia and mania. He cured these patients by psychoanalysis without seeking any sexual factors. Cases of bladder and rectum neuroses, especially in young girls, often subsided permanently when the practice of masturbation was discovered and combated.

Calcium Content of the Blood in Children.—Robles found that the calcium content in the children examined ranged from N 75 to N 90. It seemed to keep at a constant figure in the same child, when the Wright method for determination of the calcium in the blood was applied. In all such tests the time should be recorded; the findings differ the longer or shorter the time. Half a minute seems the preferable technic. His extensive tests of children with tetany failed to show any difference from normal in the calcium content of the blood.

Hospitalstidende, Copenhagen

- *Permanently High Blood Pressure.—V. Topp, p. 705.
 *Syphilis in Etiology of Appendicitis.—H. Boas and O. Weiss, p. 709.

The Prognosis with Permanently High Blood Pressure.—Topp tabulates the findings at the Finsen Institute in 164 cases of permanently high blood pressure, above 180 mm., between 1913 and 1916. Recent reports in regard to 157 show that 83.5 per cent. have died since. The surviving 16.5 per cent. had a maximal pressure of 180 to 220 and one of 250, including 4 between 40 and 49; 9 between 50 and 59; 8 between 60 and 69, and 5 between 70 and 79. There were 118 men to 39 women; 15.3 per cent. of the men are still living and 20.5 of the women. In over 60 per cent. of the patients, sclerosis of the kidneys was evident, and 84 per cent. of these patients died within two years. The survivors are all persons who are able to reduce physical exertion to the minimum.

Syphilis in Etiology of Appendicitis.—Boas examined sixty-seven appendicitis patients for signs of syphilis, but found nothing to suggest acquired or inherited syphilis in sixty-five of them.

June 11, 1919, 62, No. 24

- *Spirochetes in Paretic Dementia.—H. C. Hall, p. 729.

Spirochetes in Paretic Dementia.—Hall was never able to discover spirochetes in the brain in cases of paretic dementia until he applied Jahnke's technic. With this he showed up the spirochetes readily even when the Levaditi and Noguchi methods gave negative results. Jahnke supplemented the Levaditi technic with a preliminary treatment with uranium nitrate which Cajal recommends with his method for staining glia to avoid the necessity for staining of the nerve fibrils. The uranium nitrate affects the fibrils and the spirochetes in a different manner. In tissue treated for thirty minutes to an hour at 37° C. with a 1 per cent. solution of uranium nitrate, the nerve fibrils become incapable of taking the silver nitrate stain while the spirochetes take this stain well. The whole procedure takes three or four weeks, but the findings seem to be extremely instructive. In the two cases described in detail, the discovery of the spirochetes harmonized with the symptoms noted during life. They seem to occur in a few well defined foci, mainly in the cortex. He adds that certain biologic characteristics of the spirochetes found in paretic dementia seem to indicate that this is a specific type of the syphilitic virus, with a special affinity for the nervous system.

- *Influenza in the Pregnant and in Parturients.—F. Hauch, p. 1063.
 *Uncommonly Edematous Two Cases.—H. R. Magnus, p. 1069.
 *Catheterization in Cases of Retention.—C. Dethlefsen, p. 1071.

Influenza in the Pregnant and in Parturients. Hauch concludes from experiences at the Copenhagen Maternity that labor and delivery are very dangerous in the course of influenza pneumonia, and hence must be deferred with every means in our power. The fetus usually dies in the severer cases, and the death of the fetus renders the prognosis grave. Otherwise the pneumonia has no especial gravity during a pregnancy or in the puerperium.

Catheterization in Cases of Retention. Dethlefsen connects the catheter with a douche can of warm water and lets the water pour with force through the catheter as the latter is being introduced. This prevents obstruction of the catheter, and facilitates materially the introduction of the catheter, while smoothing out folds in the urethra lining.

DERMATOLOGY AND ASSOCIATED DIS- ORDERS OF THE MUCOUS MEMBRANES*

O. H. FOERSTER, M.D.
MILWAUKEE

One of the proper and important functions of the dermatologist is the study and interpretation of disorders of the mucous membranes, occurring either as independent manifestations or in association with cutaneous or constitutional disease. By reason of their continuity with the skin and close structural relationship, consideration of the mucous membranes ought logically to be included in a complete dermatologic investigation, a practice more often omitted than observed. The statement that they deserve investigation is particularly applicable to the oral cavity, in which the presence of lesions of the mucous membranes may serve to clarify the diagnosis of accompanying cutaneous disorders, and at times provides the key for the recognition of otherwise obscure conditions of disease.

Compared with the voluminous literature concerning every feature of the cutaneous expression of disease, that dealing with affections of the mucous membranes is disproportionately small and is to a considerable extent incidental in character. Perhaps this is a reflection of the tendency in practice to be uncertain when lesions of the mucous membranes not frankly specific are in question, and to formulate diagnostic conclusions from evidence with which we confess ourselves to be more familiar. In any event, this field offers abundant opportunity for observation and study, the results of which will be welcomed as an important addition to medicine as a whole and to dermatology in particular.

It is not proposed at this time to enter into an extensive discussion of mucous membrane disorders, but rather to point out that the subject warrants greater consideration than has been given it in teaching and practice, and that by inattention to this field much of clinical value fails of proper interpretation or goes unrecognized.

The occurrence of papules and of vesicular and exudative processes in the mucous membranes, resulting in erosions, plaques and ulcerations, is observed as part of the symptomatology of a variety of diseases. Those of especial interest to the dermatologist, aside from syphilis, are the lesions of the mucous mem-

branes which occur in association with disorders classified as typically cutaneous. Represented in this group are lichen planus, erythema multiforme, dermatitis herpetiformis, the three varieties of pemphigus, erythema lupus, lupus vulgaris, herpes and impetigo herpetiformis, mostly dermatoses of constitutional origin. Involvement of the mucous membranes is of regular occurrence in several of these conditions and may, in fact, precede the cutaneous symptoms or, in rare instances, be the only manifestation of the disease.

CLINICAL FEATURES OF LICHEN PLANUS

Lichen planus presents all of these variations. We are inclined to look on lichen planus as a typical dermatosis, and yet its lesions may be limited entirely to the mucous membranes or may exist there for a long period before the appearance of cutaneous symptoms. The case of solitary lichen planus of the tongue reported by Montgomery¹, and that of lichen planus of the buccal mucosa and tongue in a child, as recorded by Sainton and Burnier,² are instances of this unusual limitation. A tabulation made by Trautman (as quoted by Montgomery¹) of 157 cases of lichen planus of the mucous membranes, shows that the skin was primarily affected in fourteen cases, coincidentally affected in ninety-four, subsequently affected in nineteen, and that in twenty-six instances the mucous membrane lesions existed alone. In these 157 cases, the cheeks were affected in 129 instances, the tongue in eighty, the lips in thirty-five, the palate in twenty-seven, the gums in seventeen, the larynx in seven and vulva in six. The striking feature of this tabulation is the high percentage of cases in which the disease affected the mucous membranes exclusively.

Lichen planus of the oral cavity is one of the most accurately studied affections of the mucous membranes and presents fairly distinctive clinical features. Its comparatively frequent occurrence offers at least one reason for attempting to gain proficiency in diagnosis based on symptoms limited to the mucosa. The essential lesion is a papule, appearing as a convex, conical or flattened, hard, whitish-gray dot of pin-head size or smaller, without an inflammatory halo. The papules are either discrete and scattered, or arranged in groups or lines, the latter often forming a rather characteristic meshwork, with nodes at the points of intersection as described by Montgomery.¹ Circinate lesions occasionally develop by reason of the appearance of new papules at the margin of an older group, with involution of the latter, leaving a depressed, smooth, nonstriated, bluish-red center, sur-

* Chairman's address, read before the Section on Dermatology at the Seventieth Annual Session of the American Medical Association, Atlantic City, N. J., June, 1919.

¹ Montgomery, D. W.: J. Cutan. Dis. 32:481 (July) 1914.

² Sainton and Burnier: Bull. Soc. franc. de dermat. et syph. 22:260, 1911.

rounded by a delicate polycyclic border composed of tiny papules. The formation of ring lesions by central involution and peripheral extension of large papules has also been noted. Lieberthal's³ description of lichen planus as it appears in the oral cavity is concise and accurate. He says:

On the cheeks, lichen planus, as a rule, affects that part which is just opposite the interdental space and presents papules, oval or circular plaques and, most frequently, streaks or linear projections with intervening furrows. These projections are arranged in different ways, parallel to each other, convergent or divergent, passing each other in different directions and forming networks, or stellar or brush-like formations. They all show the character of the elementary papules, are opaque, sharply defined and painless. The lesions of the tongue differ somewhat. On the back they present irregular, oval or circular plaques, while on the upper and lower surfaces of the margins solitary papules are found, or more frequently, irregular or band and striplike plaques. They are, as a rule, not sharply defined, are smooth, less hard, not raised above the level of the normal surface, not glossy, but dull and grayish white. On the mucous membrane of the lips the papules form irregular plaques, and on the vermillion border groups of irregular plaques. On the soft and hard palate, and on the gums, solitary and aggregated papules are more frequent than plaques or networks. The older the process upon the mucous membranes, the more do the papules coalesce and lose their distinct outlines. The plaques and streaks lose their roughness and hardness, and at last they become so flat that there is no elevation present, but only the shiny, white discoloration resembling mucosa touched with silver nitrate. These lesions show no tendency to degenerative changes; no erosion or ulceration occurs.

The process is indolent and often persistent, and may relapse after its spontaneous disappearance.

In addition to the oral cavity, lichen planus appears also on the vaginal and urethral mucosa, and not infrequently manifests itself on the glans penis.

The clinical features of lichen planus of the mucous surfaces have been presented in considerable detail because of the difficulties at times encountered by the practitioner in differentiating the disease from syphilis. With lesions confined to the mucosa, the diagnostic skill of the expert is put to the severest test, and even with accompanying cutaneous symptoms the situation may prove confusing. Fordyce⁴ has pictured the condition thus:

The grouping and distribution of lichen planus of the skin, with its pigment changes, may closely simulate a syphilid, and if at the same time radiating, or parallel, gray or white streaks are seen inside the cheeks, with palmar and plantar papules, and swelling of the inguinal or cervical lymph nodes, the diagnostic difficulties increase. The observer may be still further confused by the absence of itching in lichen planus and its favorable response to mercurial treatment. Consideration in the differential diagnosis of lichen planus and syphilis should be given to the several phases of mucous patches, scars or epithelial changes after the involution of specific lesions, as well as to the specific and non-specific leukoplasias. Leukokeratosis in individuals who are not smokers, and from whom a syphilitic history cannot be elicited, should suggest the probability of lichen planus, and lead the observer to look for further evidence of that affection.

It has been my experience that lichen planus of the skin, attended with itching, is frequently diagnosed as eczema or scabies by the practitioner. This error can in many instances be avoided by an inspection of the oral mucosa, provided the frequent appearance of lichen planus in this location is borne in mind.

LUPUS ERYTHEMATOSUS

Lupus erythematosus may also be limited to the mucous membranes, either entirely, which is rare, or for a considerable time preceding its appearance on the skin or scalp. Its recognition under these conditions is made more difficult by variations in its clinical appearance dependent on the stage of the process. Dubreuilh,⁵ Smith⁶ and Kren⁷ draw a distinction between the appearance presented by recent and by older lesions of lupus erythematosus as observed on the oral mucosa. Their descriptions of early lesions indicate that the disorder begins as a hyperemic, bluish-red, slightly elevated spot, with indefinite outlines and, at times, a slightly eroded surface. In this stage differentiation from other acute inflammatory lesions is often impossible. Within a few days the lesion undergoes a change, the margins are slightly elevated and more distinct in outline, and delicate vascular striations are observed converging toward the center of the lesion, which is now depressed, eroded, and often covered with an adherent yellowish pellicle.

In a later stage the central erosion increases in depth and is either converted into a thin, flat scar, or is covered with epithelium, with the formation of closely set, bluish-white puncta or striations converging centrally. On the lips the striae may be arranged in parallel lines or in the form of a delicate network. Coincident with the appearance of these whitish striations, the lesion loses its inflammatory character and enters on the stage of atrophy and quiescence. It is not unusual, however, for the lesion again to enlarge by peripheral extension and to show recurrent central erosion at intervals. This description applies especially to patches as they appear on the buccal mucosa, which is the site of predilection.

Kren⁷ has given a clear and accurate account of the condition as it is observed on the lips. He says:

The plaques, which may by continuance rapidly involve the entire lip, have the same margins with similar vascular ectasia or similar fine white tracery (as observed on the buccal mucosa). The delicate network of white striae is especially distinct within the margins of lesions on the vermillion of the lip. This is a feature which is observed repeatedly and which has not been given sufficient prominence in descriptions of the affection. The color of the lip is violaceous; the lip is slightly swollen and often everted. As a rule, in recent cases the lip is so heavily covered with scalelike, large, thin, epithelial lamellae and with bloodcrusts, that the details just described are seen only in part or not at all. The lip then presents the appearance, as described by Dubreuilh, of having been painted with collodion which is peeling off. After maceration of the lamellae and crusts, irregular red areas with concave margins may be observed in the violaceous labial mucosa, which is stippled with white dots. Especially noticeable is the readiness with which bleeding of the affected labial mucosa occurs upon slight movement, a condition which is rarely observed in the oral mucosa.

I have had the opportunity to observe during several years an instance of lupus erythematosus, in a young woman, with two lesions on the mucosa of the lower lip. These had been present for more than one year before three additional patches appeared on the scalp, and they still persist long after the disappearance of the scalp lesions. At irregular intervals both lesions on

the lip become edematous, with reddened, elevated margins and central erosion. On subsidence of the inflammation the lesions again assume their indolent form, with slight marginal infiltration and central depression and atrophy.

CONFUSION WITH SYPHILIS

The symptomatology of lichen planus and of lupus erythematosus, as observed in the mouth, has been described in more or less detail because these two disorders may present features requiring differentiation from syphilis. If the lesions appear on the mucous membranes primarily, and especially if they remain limited to the mucosa, the aid in diagnosis which might be afforded by the presence of cutaneous lesions is not available; knowledge of the symptomatology as described will then prove valuable by providing distinguishing data.

While other dermatoses than lichen planus and lupus erythematosus may exhibit lesions of the mucous membranes, these are seldom of such character as to be confused with those produced by syphilis. They are generally of short duration, and in their essential features are reproductions on the mucosa of the coincident cutaneous lesions, modified by location. An exception must be made, however, with respect to erythema multiforme and pemphigus, in which the occasional limitation of lesions to the mucosa and their clinical appearance may simulate the mucous patches of syphilis, and especially in pemphigus vegetans, in which the oral mucosa and perigenital and anal regions may be simultaneously affected. In these diseases the lesions of mucous surfaces will almost invariably present evidence of their vesicular or bullous origin by shreds of epithelium which persist at some part of their margins, though careful examination may be required to reveal them. In addition, these lesions are usually painful, bleed readily, are always superficial and not infiltrated, are surrounded by an inflammatory zone, and may present polycyclic contours by fusion of adjoining lesions. The polycyclic outline and collarette of epithelial shreds are also features which serve to differentiate relapsing herpes of the mouth from mucous patches, as pointed out by Fournier.

OTHER AFFECTIONS PRODUCING LESIONS

The mucous membranes may participate in the symptomatology of a number of other dermatologic conditions, too numerous for detailed discussion at this time. It is well to recall, however, that dermatitis herpetiformis may present lesions on the tongue, lips, cheeks, conjunctiva, prepuce and labia, usually of marked inflammatory nature and attended with burning pain. Urticaria, angioneurotic edema and purpura often involve the mucous membranes of the mouth, nose and alimentary tract. Medicinal agents, especially antipyrin, have been known to produce erosive lesions of the mucosa, and iodine has been responsible for ecchymotic and gangrenous processes. Engmann⁹ describes seborrheic eczema as occurring on the conjunctiva, oral mucosa, tongue and introitus vaginae, and also discusses the subject of affections of the mucous membranes in relation to skin diseases in a comprehensive manner. Acanthosis nigricans, made known to us by Pollitzer, affects the lips and mouth with considerable regularity, and impetigo herpetiformis may be preceded by lesions of the oral mucosa.

Recently, Mook¹⁰ has described a series of cases of pemphigoid dermatitis following vaccination, several of which presented oral lesions; an allied condition was described by Howe,¹¹ six out of ten of his cases ending fatally, with marked involvement of the oral mucosa.

Several of the constitutional diseases, scurvy, pellagra, acute leukemia and pernicious anemia, not infrequently affect the mucous membranes, and it may devolve on the dermatologist to establish the diagnosis. Tuberculosis, syphilis, and malignant disease of the mucous membranes, leukoplakia and the mucous membrane lesions occurring in the course of the acute exanthems will only be mentioned here, for their importance in relation to the general subject is so evident as not to require further comment at this time or place.

GEOGRAPHIC TONGUE

There remain three conditions to which, it appears to me, attention can be directed profitably at this time. One is geographic tongue, wandering rash of the tongue, or exfoliatio linguae areata, regarding which some confusion appears to exist, largely a matter of nomenclature, in my opinion. It is described in most textbooks as a rare disease, occurring chiefly in young children. My experience with this condition may be entirely at variance with that of other observers, for I have encountered it most often in adults and only very rarely in children. During a period of service as member of a medical advisory board, I examined carefully the mouth and tongue in every one of 2,800 men referred for various physical defects, and found the geographic tongue in twenty. Most of the men so affected were not even aware of the presence of the disease. While in service at a base hospital several instances of it were seen in soldiers sent for treatment under the erroneous diagnosis of syphilis, or in soldiers presenting themselves voluntarily for advice as to the condition. The routine examination of the mouth and tongue of every patient may account for my observation that the disorder is not a rarity. A characteristic feature of the lesion is the yellowish or yellowish-gray color of the slightly elevated border, contrasting sharply with the red center.

MOELLER'S GLOSSITIS

Harris¹² has recently called attention to the uncommon condition known as Moeller's glossitis, or chronic superficial excoriation of the tongue, and described two cases observed by him. His publication has led to the recognition of additional cases, and to stimulate further interest it appears desirable at this time to direct attention again to this important and sometimes grave disorder. Harris gives this condensed picture of Moeller's glossitis:

An affection of the tongue occurring in middle-aged adults, principally women, and affecting especially the tip and edges, but also the dorsum of the tongue; but at times also the inside of the lips, cheek, hard and soft palate, and characterized subjectively by a sensation of burning pain, and objectively by the presence of intensely red, sharply defined, irregular patches, in which the filiform papillae are thinned or absent, the fungiform papillae are swollen, and the stratum corneum desquamated. The condition shows periods of exacerbation and lessened intensity, but is very resistant to treatment and tends to persist. The severe pain caused by eating interferes with nutrition and may lead to grave consequences.

10. Mook, W. H.: *J. Cutan. Dis.* 33: 667 (Oct.) 1915.

11. Howe, J. S.: *J. Cutan. Dis.* 21: 254 (June) 1903.

12. Harris: *J. Cutan. Dis.* 33: 742, 1915.

9. Engmann, M. F.: *J. Cutan. Dis.* 22: 412 (Sept.) 1904.

Though its symptoms are distinctive, Harris found the disease confused in the literature with geographic tongue, neuralgia of the tongue and lichen planus.

VINCENT'S DISEASE

It has been impressed on me by experience that, with the return of our troops to their home communities, Vincent's disease will probably become an important factor in the differential diagnosis of lesions of the mouth and other mucous surfaces. Attention has been called to the increase in the number of cases of Vincent's disease since 1915 in Canada¹³ and England, among both the soldiers and the civilian population; but similar statistics as to the prevalence of the disease in this country are not available. As it is a communicable and curable affection, its early recognition is a matter of considerable importance. Vincent's angina has been a widespread, though not common disease in this country for many years, and small, localized epidemics have at times occurred. Among the overseas troops, "trench mouth" has been identified as Vincent's disease, and statistics from one British military hospital in France state that it represented 23 per cent. of all throat complaints. Most of the patients with this affection whom I have seen and who had been overseas gave a history of trench mouth, usually described as of moderate severity; recent attacks were probably recurrent.

Vincent's disease may appear on the tonsil as a deep ulceration; on the ramus of the lower jaw posterior to the last molar tooth as a localized ulcerating patch; as a general mouth infection involving almost the entire mucosa, pharynx, and at times the tongue, or remain limited to the gums, where it is often primary and may be mistaken for pyorrhea alveolaris.¹⁴ Mild cases tending to chronicity occur as tonsillitis or gingivitis of moderate degree, or on the cheeks and lips in shredlike patches resembling the condition observed in those who habitually bite the lip or cheek. These mild types may develop into severe attacks, with the formation of sloughing, seriginous ulcers covered with a heavy, pulaceous, creamy, often adherent pseudomembrane. The ulceration may be superficial, or deep and destructive; it may spread with rapidity, and involve large areas of the mucosa. The breath is fetid, the glands are swollen, and the patient often presents a pallid or yellowish appearance, even in cases of moderate severity, though the systemic reaction is often less than would be expected.

The disease may also produce ulceration and gangrene of the vulva, conjunctivitis and an ulcerative balanitis. Greeley¹⁵ has recorded a case with coincident purpuric eruption and bleeding from the nose and gums, in several attacks, ending fatally.

The spirillum of Vincent and the associated fusiform bacillus are recognized as the causative agents of the disease, and can be readily detected in smears. The organisms are also readily seen in dark-field preparations, and I have made frequent use of this method of diagnosis. The clinical resemblance to diphtheria is occasionally marked, and cultures should be made in all doubtful cases, as the two diseases may coexist.

The predicted increase in the number of cases of Vincent's disease indicates that it will enter more fre-

quently than heretofore into the differential diagnosis of syphilis, and that familiarity with the various phases of its symptomatology will be required of the dermatologist. The possibility of confusing Vincent's disease with syphilis is not as remote as might appear, for the similarity of the lesions to mucous patches may be striking in the cases of moderate severity, and search should always be made for the organisms.

The possibility of coexistence of the two diseases should be kept in mind, as well as the fact that mercurial treatment may arouse to activity quiescent types of Vincent's disease in the syphilitic.

ACCESSORY NASAL SINUSES OF CHILDREN *

SEYMOUR OPPENHEIMER, M.D.

NEW YORK

The views that I have expressed in several previous publications, dating back to 1912, as to the frequency of accessory sinus diseases in children, hold at the present time with additional emphasis. Subsequent investigation of anatomic specimens and references to the work of others seems to demonstrate that the accessory nasal sinus development occurs at a much earlier period than is generally considered by most investigators, and it is accepted that their variation in size, shape and position at different ages, up to the period when they assume the adult type, is extreme.

SINUSITIS IN THE CHILD

From a careful study of the early anatomic development of the sinuses, it seems probable that many cases of meningitis are the result of unrecognized inflammation of some of the sinuses, as the symptoms of sinusitis are more or less obscure in children. That this should be so can readily be appreciated from the structure of these parts at an early age, for they are surrounded by much softer bone than at a later period of life; there is a more profuse development of the lymphatic and vascular systems, and the mucosa is in most intimate relation with the osseous tissue, so that slight inflammation of the former must produce some pathologic change in the latter. My experience has been that in the child, chronic sinusitis is common, and it will be found on careful examination that many instances of postnasal catarrh in the child are but symptoms of some inflammatory condition of the adjacent sinuses.

DEVELOPMENT OF THE SINUSES

The reasons for the development of the nasal accessory sinuses have been defined by various authors with varying theories. Killian believes that the development of this area depends on the inherent biologic characteristics of the cells which go to form the various structures in this area. Coffin and Freres, however, explain the development on a physical basis. They believe that the reabsorption of bone is due to variations in air pressure, particularly that of expiration; that the principal growth of the sinuses begins after breathing occurs; that there is a distinct similarity between the effect of air pressure on the

sinuses and on the alveoli of the lung, and that a constant change of air pressure in the sinuses, and, finally, the direction of the inspired and expired air bear a relation to the anatomic formation of the nose. These two authors also point out that children having adenoids present poorly developed sinuses, because of the lack of normal air pressure in the nose during expiration.

Functions.—The functions of the nasal accessory sinuses have been subject to considerable controversy, and no particular theory as to the physiology of these cavities has as yet been universally accepted. Whether the sinuses are the remains of rudimentary structures, which, in lower animals, serve as adjuncts to the act of smelling, or whether these cavities evenly distribute the inspired air and thus help olfaction, is still open to discussion, as well as the suggestion that the pneumatization and extension of these cells serve to lighten the bones of the skull in order that proper poise and counterpoise, may be maintained. The contention that they are an adjunct to respiration by moistening the inspired air is not supported by histologic findings, as there are no mucous glands in the mucosa of these cavities.

Early Appearance.—In connection with the anatomic development, it should be remembered that the maxillary sinus is well defined, although rudimentary, at birth, and even in the fetus it is found about the fourth month, so that inflammation of this sinus at an early age is not infrequent. From this early form, in which it has a triangular shape, it undergoes but little change until the second dentition, when the development of the molars and bicuspid teeth play an important part in its relation to the bones of the face. Previous to the completion of the first dentition, the odontoblasts are in the most intimate relation with the floor of the sinus, which continues to develop, but does not reach the adult type until about the twelfth year. The thickest wall is then found to be formed by the body of the superior maxilla posteriorly, while the orbital wall superiorly is of extreme tenuity. Much earlier, however, accessory foramina are found, as in the adult, and the stomata open into the middle meatus at the posterior end of the semilunar hiatus.

IMPORTANCE OF CELLS

Most important in the child are the inflammatory affections of the ethmoid cells, these cells and the antrums being more frequently involved than the frontal and sphenoidal sinuses. Evidences of the ethmoidal area are seen in the fetus about the eighth month; but development into distinct cells does not commence until the fourth year, and from that period on these tissues are susceptible to morbid changes, the cells reaching their maximum development about the twentieth year. In the child, as in the adult, the middle turbinate body is essentially a portion of the ethmoid area, although its anterior end is thinned out, is small and runs parallel to the perpendicular plate, so that the lower border is deflected inward. At about the eighth to the tenth year one finds that the ethmoidal ostia open into the nasal meatuses, and for surgical purposes, and especially in the recognition of morbid changes, the cells can be grouped into an anterior mass communicating with the middle meatus, while the posterior group opens into the superior meatus.

The anterior group is by far the more important, as its stomata are found along the semilunar hiatus and the fissure between the ethmoidal bulla and the inferior turbinate body, at a location at which infection from intranasal morbid changes most frequently takes place. The anterior cells are more numerous than the posterior, although the latter are larger as regards the capacity of the individual cells, and their stomata are much less in size than those of the anterior mass. As the internal wall of the orbital fossa forms the eternal boundary of the ethmoid, the possibility of orbital symptoms, as a complication of ethmoidal infection, is apparent. In operating on this region, this relationship must be borne in mind on account of the extreme thinness of the ethmoidal orbital wall, and the danger of injuring the contents of the orbital cavity.

FRONTAL AND SPHENOIDAL SINUSES

Previous to the seventh or eighth year, the frontal sinus is usually not developed, although not infrequently it is present as early as the fifth year. Before puberty, it does not extend far up in the frontal bone; then a marked change takes place until the eighteenth year, when its full development is accomplished. The anatomic and surgical relation differs in no way from that in the adult, except that its relation to the cranial cavity, on account of the thin posterior wall, is most intimate; and this must be considered in relation to inflammatory processes.

The sphenoidal sinus may show a definite cavity as early as the third year, while, by the seventh year, it is well developed; and although its inflammatory changes have not been as much studied as have those of the other sinuses, I am of the opinion that it is more frequently involved than is usually thought. Its lateral walls are largely within the intracranial cavity, and this deserves special consideration in relation to the development of obscure cases of basal meningitis, as do also its intimate relations laterally and superiorly with the internal carotid artery and cavernous sinus.

RECOGNITION OF SINUSITIS

The recognition of sinusitis in the child is more difficult than in the adult, as the symptoms are usually obscure and rarely characteristic; and it is unusual to have a single sinus involved to the exclusion of the others, the rule being that more than one sinus is affected at the same time. One can well appreciate the difficulty of differentiating individual inflammatory areas under such circumstances. When the upper sinuses are the seat of a purulent inflammation, the discharges may reinfect those lower down, and especially the maxillary antrum, so that the soft tissues around the stomata are kept irritated and swollen, and it becomes most difficult to differentiate the exact underlying faulty condition.

INVOLVEMENT DUE TO INFECTIOUS DISEASE

The frequency of occurrence of the infectious diseases in childhood, and the concomitant inflammatory changes of the nasal mucosa, explain why the sinuses are involved during this period, and they are involved particularly in influenza, scarlet fever, measles and pneumonia. In the vast majority of cases there is a primary inflammation of the nasal mucosa, and the sinuses involved become so from a direct extension of this inflammation, irrespective of its basal cause, the swelling of the soft tissues around

the sinus opening causing the secretions to be retained as a result of the stenosis which is produced.

In the new-born child, antral sinusitis may occur as a consequence of infection by vaginal discharges from the mother, or from injury—the result of instrumental delivery—and the resultant purulent inflammation involves the soft osseous antral walls. In my experience, this condition arising in small children from these causes or from others is a true sinusitis, as well defined as that found in the adult, and it is not a tuberculous caries or osteomyelitis, as has sometimes been claimed. As a rule, affections of the antrum occur during the second dentition, while, infrequently, errors in the development of the teeth may act as an exciting cause of the empyema.

The ethmoid labyrinth in the older child is especially liable to become involved in all inflammatory affections of the nasal mucosa, and in coryza; and in the contagious diseases of childhood these cells are affected in practically every instance, frequently accounting, to my mind, for suppurative ethmoiditis in later life, which has, in reality, existed from early childhood.

DRAINAGE

The nasal accessory sinuses are able, normally, to drain themselves continuously by virtue of the fact that, although their outlet openings are not in every instance situated at the most dependent portion of the cavity, their mucous membrane is furnished with ciliated epithelia, which constantly waft their cilia in the direction of the outlet. Furthermore, the normal openings of some of these cavities are in the most dependent portion of the sinus when the head is in the upright position. In the ethmoidal tract, the drainage may be exceedingly simple or intricate; the individual cells may drain by opening one into the other or directly into the nasal chamber.

BACTERIOLOGY

It is reasonable to presume that the bacteria found in the nasal accessory sinuses of infants and children during inflammatory conditions should be the same as the flora present in these cavities in the adult. Torne, as early as 1903, showed that without exception healthy sinuses were found sterile in cadavers within two hours after death. Zarneo tabulated the organisms in the order of their importance as infecting agents in accessory sinus disease as follows: *Diplococcus lanceolatus* (pneumococcus), staphylococci and streptococci, influenza bacillus, pseudodiphtheria bacillus, Friedlander's capsule bacillus, *Meningococcus intracellularis*, *Bacterium coli*, *Bacillus pyocyaneus*, *Bacillus pyogenes-fortidus*.

According to Turner, in twenty-two cases of acute and chronic fronto-ethmoidal sinus disease, the pneumococcus was isolated in eight (36 per cent.), *Streptococcus pyogenes* in nine (40 per cent.), and the staphylococcus in ten (45 per cent.). An organism which he called the influenza bacillus occurred in one case. In forty-three cases of maxillary sinus disease, the pneumococcus was present in thirteen (30 per cent.), *Streptococcus pyogenes* in thirty-three (76 per cent.), staphylococci in thirty-four (79 per cent.), *Bacillus influenzae* in one, *Bacillus tuberculosis* in one, and *Micrococcus catarrhalis* in two. Tabcock, in a recent investigation on the bacteriology of sinus infections, has shown that in fifty-three acute cases, pneumococci of the various groups

were found in thirty-two instances, streptococci in five, staphylococci in thirty, and *Bacillus influenzae* in four. A number of other organisms which are not ordinarily pathogenic were also found, but did not occur alone. In forty-seven chronic cases, pneumococci were found six times; streptococci, nineteen; staphylococci, thirty-eight; *Bacillus influenzae*, twice, and many other organisms which were not supposed, however, to be pathogenic.

STAPHYLOCOCCI AS INFECTING ORGANISMS

We have observed in the results of all these investigations that staphylococci occur in equal, if not in greater frequency than the other organisms mentioned. The question of whether or not staphylococci are of infective consequence, when present in the secretions of infected nasal accessory sinuses, has arisen, therefore, many times in our mind. To answer the question we endeavored to determine whether or not the staphylococci isolated from the purulent discharges procured from the nasal accessory sinuses were pathogenic to rabbits.

The nasal chambers were irrigated with a sterile solution of sodium chlorid. The secretions were then sucked out of the nose into a sterile tube, and cultures were made from this pus on agar plates. The staphylococci were identified, by means of their staining characteristics with Gram's stain, and by the color and the general appearance of their colonies. Of seventeen specimens of pus secured from seventeen patients suffering from acute sinus disease of one or more cavities, staphylococci were recovered in eleven. In four, *Staphylococcus pyogenes-aureus* was found; in eight, *Staphylococcus albus*, and in two, *Staphylococcus citreus*. *Staphylococcus aureus* and *albus* were recovered together from three specimens.

In endeavoring to ascertain whether these organisms were pathogenic to rabbits, we first determined the maximum dose of nonvirulent staphylococci which the animal could be given intravenously without causing its death. For this purpose agar slants of uniform size were made, and the organisms were grown on them for twenty-four hours. A sufficient amount of sterile physiologic sodium chlorid solution was then poured into the tube up to the top of the slant, with the tube held in the upright position. The organisms were then scraped off the surface of the agar with a platinum loop, and the solution and the bacteria were poured into another tube and thoroughly shaken. Five-tenths c.c. of such suspension of nonvirulent staphylococci was the maximum dose that could be given to a rabbit intravenously without causing its death. Twenty-four hours after the rabbits were infected, blood cultures were made by paracentesis cordis and every twenty-four hours thereafter, until the cultures were found sterile or the animal died.

EFFECT ON RABBITS

One animal that received *Staphylococcus aureus* gave a sterile blood culture within three days. Another, whose blood culture was positive after twenty-four hours, died the following day, and on necropsy an extensive hemorrhage was found in the pericardial sac. The animal died as the result, probably, of the trauma incident to cardiopuncture. In a third, the blood culture remained positive until the animal's death, which was six days later, and on necropsy a purulent pericarditis and abscesses of the liver and kidney were found. Pure cultures of *Staphylococcus aureus* were recovered from these lesions. The fourth animal was found dead one day after infection. Free fluid in the pleural cavity was found,

as well as an abscess of the liver. Cultures from these produced not only *Staphylococcus aureus*, but, in addition, a gram-positive bacillus. All of the rabbits that were infected with *Staphylococcus albus* gave negative blood cultures in from three to seven days. In one case, the animal died two days after the blood culture was found sterile. There was marked congestion of the right lung, dilatation of the right heart, the left heart being empty, and there were a few grayish-white spots in the substance of the left kidney. Unfortunately, no cultures were made from these lesions. In the two rabbits in which *Staphylococcus citreus* was injected, the cultures were found sterile after the third day.

It can readily be seen, although the number of specimens examined is small, that only one out of seventeen cultures of staphylococci could be considered as definitely virulent. Our presumption, therefore, is that in the great majority of cases staphylococci are not the primary infecting organisms, but are secondary invaders which supplant the offending organism and prolong the symptoms.

THE DIAGNOSIS

The recognition of the various sinus affections in the child is more difficult than in the adult, as the subjective symptoms are not clearly defined. Transillumination is of value, but comparative studies must be made, as the area of light and shadow is rather different than in the adult. The use of carefully made roentgen plates, however, is of great service, especially as regards the presence of pus in the antra or frontal sinuses; and, previous to the tenth year, the use of the roentgen ray is the most valuable diagnostic medium that we possess. The presence of frequent headache should always occasion suspicion of sinus inflammation, and especially when the parts are tender to touch over the sinus involved, bearing in mind, however, that localizing pain with any degree of accuracy is difficult in the very young. In acute sinusitis, pain of an aching character is almost invariably present at some time during the course of the inflammation, but in chronic cases it is very frequently absent, unless the secretions are retained under pressure, when it may become most intense.

A marked symptom of great diagnostic value, when present, is the cessation of pain with the appearance of a free nasal discharge, and the return of the pain when the discharge lessens or temporarily ceases. The presence of a discharge, especially if unilateral and purulent, or semipurulent, in character, is always of diagnostic value, and especially if intermittent. If there is lymphoid tissue in the vault of the pharynx, most marked on the side from which the discharge comes, it will often be found that the adenoids are not the sole source of the continued coryza from which the child suffers, but that there is, in addition, a sinusitis. Location of the source of the discharge is of great value in determining which sinus is affected, and the method of ascertaining the source differs in no way from that employed in the case of the adult, which is so well known as to require no further discussion.

Aprosexia and disturbance in the general health are more or less inevitable concomitants of chronic purulent sinusitis, while complications, as in the adult, are not as frequent, although orbital symptoms are not uncommon. In the so-called strumous child, with whom there is a purulent nasal discharge, with excoriated upper lip and marginal blepharitis, and frequently with corneal ulcers, purulent sinusitis,

usually of the antrum and of the ethmoid cells, exists; and while serious organic osseous changes are not present, when they do occur the ethmoid structures are most frequently involved. In purulent inflammation of these sinuses, and especially in that acute, fulminating type sometimes seen, serious orbital complications may ensue as a result of pathologic changes in the correlated vascular sinuses, with the development of thrombosis of the cavernous sinus and resultant pycnia, meningitis and death. In the milder form, a symptom not uncommon and always of diagnostic value is edema of the eyelids from vascular pressure. In inflammatory processes affecting the maxillary antrum, it is not uncommon to find some involvement of the osseous structures of the superior maxilla, if the purulent sinusitis is long continued; but in the majority of instances the affection presents rather a benign course and, only too frequently unrecognized, it is treated as "nasal catarrh." After the nasal chamber has been cleansed the reappearance of pus in the middle meatus is indicative of antral suppuration, but in older children puncture of the lateral nasal wall of the antrum is necessary to recognize the condition present.

CLOSE RELATIONSHIP

Inflammatory changes in the ethmoid structures, a result of neglected rhinitis, are frequently found. It has been my experience that isolated sinusitis is uncommon. In younger children, the antrum also is apt to be involved, while in older children the frontal sinus may be simultaneously affected. On account of the relation of the complicated ethmoid system to the other sinuses, and of the fact that pathologic changes occur here so frequently as a result of the infectious diseases of childhood, it will be found that this sinus is the primary source of infection in the great majority of cases of pansinusitis, and that this relationship is especially emphasized on account of the rather intimate connection of the various stomata of its component cells with the other sinuses, so that the presence of a purulent discharge which does not, to a greater or less degree, involve other sinuses, is almost impossible.

As a result of the late development of the frontal sinus, as has been pointed out previously, chronic changes are unusual; but its involvement in the older child during acute intranasal inflammation is much more frequent than is currently considered. The recognition of inflammatory changes in this region does not differ from that in the adult, and the presence of pus in the middle nasal meatus will aid greatly in establishing the diagnosis, although it may be easier to eliminate suppuration of the frontal sinus than to define its presence.

PURULENT SPHENOIDAL SINUSITIS

The recognition of purulent sphenoidal sinusitis is by far the most difficult, as it is practically always combined with ethmoidal changes, and the symptoms are not characteristic. Severe occipital or vertical headache, with more or less dizziness, is suggestive of retained secretions in this sinus; the discharges are scant and usually become inspissated in the nasopharynx or along the posterior portion of the vomer and floor of the choanae, and it will not infrequently be found that the condition cannot be recognized until exploration has been made of the interior of the sinus. In the young adult, however, the exploration should

not be made until the presence of other sinus affections of a purulent character has been eliminated.

The routine use of the pharyngoscope in young children has disclosed a surprisingly large number of cases of posterior ethmoidal and sphenoidal suppuration which would have remained unrecognized by any other method of examination.

Most important is the fact that these inflammatory invasions mean a radical disturbance of the entire drainage system of the nasal interior, and all treatment, whether conservative or radical, must rest on this basis. The relation of focal lesions in the accessory nasal cavities of children to systemic diseases, such as arthritis, endocarditis and nephritis, must be considered of an importance equal to that of the lesions occurring secondary to tonsillar and dental disease. Dr. Dean, the chairman of this section, has a very valuable contribution on this subject.

FIRST MEASURES IN TREATMENT

In treatment of sinusitis in the child, the aim ought always to be to destroy as little tissue as is consistent with obtaining permanent results, and, as far as possible, the intranasal mucosa should be preserved if operative procedures become necessary in the individual case. Palliative treatment will permanently cure the majority of acute sinus inflammations when such treatment is intelligently directed toward free drainage.

Previous to the employment of surgical measures, therefore, the use of warm alkaline sprays and of weak epinephrin solution to reduce the congested mucosa, with, if the case is severe, rest in bed, the employment of laxatives and such general measures as may be indicated in the particular case, will often produce the most happy results; and in this connection it should be remembered that the tendency of acute sinusitis is toward cure, and the use of the measures outlined will not infrequently remove the inflammation when operation would have been resorted to unnecessarily, with possibly much less satisfactory results.

In these instances in which the sinus disease has continued and resists treatment, it will often be found that the general health of the child was more or less seriously affected previous to the development of the nasal affection, as a result of the original disease causing it; and until proper care of the general health is instituted, local measures alone will not be of great avail.

The employment of some type of suctional, negative pressure apparatus, applied intranasally for freeing the nose and ostia of secretions, proves very beneficial. The congestive hyperemia which is thereby induced is oftentimes decidedly curative. I have had no experience with the employment of autogenous vaccines in the treatment of sinus disease of children, but believe they probably have the same relative value as in the adult. The question of dosage must, however, be carefully considered.

I believe intranasal treatment to be indicated primarily in all cases of sinusitis in children; but it should be strongly emphasized that the turbinal tissue should be preserved; and while it is necessary at times to remove the anterior end of the middle turbinated body, the removal of its entire structure to reach the stomata of any of the sinuses is not warranted. When possible, drainage should be obtained through the natural openings, and to accomplish this it is proper

to remove as much of the osseous tissue at such points as may be required.

When the frontal sinus is involved, its relation to the anterior group of ethmoid cells is such that attention must be paid to them before the inflammation of the mucosa lining the frontal sinus will subside.

When the antrum is diseased inflammatory changes, as a rule, readily subside under ordinary treatment; but in obstinate cases, after fracturing and pushing aside the inferior turbinated body, a large opening should be made through the inferior meatus into the sinus, and the parts drained in this way, the question of whether or not irrigation is advisable is to be decided by the character and chronicity of the purulent discharge.

OPERATIVE PROCEDURE

In certain fulminating forms of sinusitis in the child, and in persistent suppurative cases resisting endonasal treatment, with marked impairment of the general health or other violently acute symptoms, an external operation will be indicated. The physician must bear in mind, however, that before any radical external operation on the child is undertaken, a most careful examination should be made for any morbid changes in adjacent areas which may be keeping up the sinusitis by interfering with drainage, as it has been my experience that in not a few instances treatment for a considerable time may be of no benefit until a hypertrophy of the middle turbinated body has been removed, or a lymphoid mass in the nasopharynx, which has acted as a constant source of reinfection. It should be emphasized that any enlargement of the middle turbinated body is a serious obstacle to the cure of inflammatory changes in any sinus, and until it has been relieved the sinusitis will prove most obstinate to treatment.

Free drainage must be secured before a cure can be obtained, and if intranasal treatment fails to obtain such a result, then whatever radical operation may be selected should be performed. It should also be emphasized in this connection that free drainage means free nasal respiration, and this is another prominent factor that must be taken into consideration in the surgical treatment of these conditions. In addition, it is essential that when pus is found in any of the sinuses it must be evacuated as a surgical principle, and granulations and necrosed tissues must be thoroughly removed. On this basis rests the surgical treatment of all chronic sinus affections, with the various modifications of technique in the care of the individual sinuses dependent on the peculiar anatomic structural characteristic of each.

When the external radical operation on the frontal sinus is under consideration, it is essential, therefore, as a preliminary step, to remove the anterior portion of the middle turbinated body in order to secure thorough drainage, and not infrequently this procedure may bring about a cure. The external operation on the frontal sinus in the young should be performed with the greatest reluctance in the absence of definite external or intracranial symptoms. In those cases in which the frontal sinusitis has been unrecognized, a fistula may have resulted, and the condition possibly has been treated as a dacryocystitis. The only method by which relief may be obtained is by thoroughly opening the sinus, externally clearing out the anterior ethmoid cells, which are always involved, and obtaining free drainage through the nasal chambers.

OTHER METHODS

In children, the antrum rarely requires external operation, as opening the lower nasal fossa with irrigation is usually sufficient to obtain a cure of the suppurative. In young children, operative work on the maxillary antrum must be performed with great caution, on account of the relation to the teeth at this age. Such procedures, during the formative period of the teeth, are apt to result most disastrously.

As a result of these studies it has been my experience that a radical external operation for the relief of purulent sinusitis is rarely indicated and is not productive of as satisfactory results as the more conservative intranasal procedures. Should indications arise however, demanding such external surgical interference, the same type of operative attack applies as in the adult.

45 East Sixtieth Street.

ABSTRACT OF DISCUSSION

DR. CHARLES GILMORE KERLEY, New York: In my professional work I have been unable in several instances to induce the laryngologist to make a diagnosis of sinusitis in children where I thought it ought to be made. It seemed to me that with the rhinologists and laryngologists sinusitis in the child was sometimes overlooked. This was not the fulminating case, which is easy to diagnose. The cases that come to me as a pediatricist are those that have often gone through the hands of the laryngologist. As one mother expressed it, the laryngologist had cut out everything in sight and out of sight, and still the child had a persistent running nose. She told me that the discharge was enormous and claimed that it took three handkerchiefs to make the trip to my office and back, a period of five hours. She showed me a handkerchief, and it was filled with a secretion, moist and of a lightish yellow color, showing that it was purulent. I told this mother that her child had sinus disease. Whereupon she told me a laryngologist had sent her to me because he had finished with the case and it was up to me to build up the child. This boy was a bright, normal, husky boy. He had good blood, his urine was normal and yet he had this persistent discharge. What did he have? He had a multiple infection, a multiple sinus infection without any damning back of secretions. Headache of obscure origin is a prominent symptom in these cases. When a child has headache, when he complains of pain, he does not deceive. Pain complained of by a child always means pain, and headache is a frequent symptom in the sinus cases. Another symptom is a persistent fever. A child has a fever that ranges from 99 to 101. Perhaps the condition has continued for several weeks. We examine for pyclitis, for tuberculosis and other conditions that might cause a persistent slight elevation of temperature. Sinusitis of a mild type has to be considered in making a diagnosis when there is a persistent temperature elevation extending over a considerable period of time. Another point that has been impressed on me in connection with work with children is that there are various diseases of adults that are acquired in childhood. Pyclitis is one. I am confident that children may have sinus disease, which, because of the obscure characteristic symptoms, is not recognized and is carried into adult life.

DR. J. M. McTIERNAN, New York: Several years ago I heard Dr. Kerley ask for some definite information as to sinus conditions in children, and I kept a record of 197 cases referred to me for removal of tonsils and adenoids. I found an almost normal nasopharynx in eighteen cases. These patients had a chronic discharge from the nostrils, a pale thickened membrane and were marked mouth breathers. Where sinus complications exist, if a saline solution is used first to wash out the nasal cavity and then a few drops of epinephrin are used, often the diagnosis can be made. I have seen headache and malaise in children relieved entirely by the treatment of sinus conditions. However, all mouth breathers are subject to headaches. I cannot agree with Dr.

Oppenheimer that it is the frequent headache which is a symptom of sinusitis in a child. I believe that a persistent, chronic headache, that headache for which a child so often wears glasses without relief, is the characteristic headache which signifies a sinus condition. I had one case where a chronic headache had existed since the patient was 8 years of age, and it was relieved when he was 16 years of age by taking off the sphenoidal wall at the right side, although the cavity had been washed out at different periods for several years.

DR. EMIL MYER, New York: I want to call attention to one form of this affection that Dr. Oppenheimer evidently overlooked, and that is the infection of the antrum and ethmoid in the very young child, the infant. There are only a few cases on record. I believe I was among the first to call attention to that many years ago, and in looking up the few cases which were recorded it was remarkable to observe the similarity of the symptoms. Each one of these patients had a curious opening on the cheek and a foul-smelling discharge from the nose. In those instances there is only one thing to do, and that is to enlarge the already existing opening and curet entirely through the nose and cleanse it. This case occurred before the day of the roentgen ray and before we knew anything about the bacteriology of it, but the chairman in his article on affections of the accessory sinuses in children last year mentioned that class of cases, and I believe it should be recorded in connection with the kind of cases mentioned by the speaker.

SIR ST. CLAIR THOMSON, London, England: This is a very important question, because we have not yet realized the connection between rhinitis and sinusitis in infancy and childhood and the atrophic rhinitis and ozena of later life. I would suggest to those in active practice that they try to get what we have long been working for, that is, postmortem examinations. We should get the pathologists in every hospital to open all the sinuses in every case that comes to postmortem, it is an operation that can be done without special equipment and it should be done as systematically as opening the other chief cavities of the body. Of course, the cases we should like to see are those that end fatally and suddenly as the result of an accident, because it will for some time be difficult to say whether the pus found in the sinuses of a patient dying of an ordinary disease, say bronchitis, dysentery, typhoid fever or pneumonia, is merely a part of the death process and not a primary focus. I throw that out as a suggestion. Sinusitis in children can be divided into those cases that are due to a focus of infection in the adenoids, and those where the focus is somewhere else. As to the infection which comes from somewhere else much work has been done in England to show that cases which we are apt to call sinusitis are really cases of osteomyelitis of the superior maxillary. Speaking of adenoids, Sir William Osler, who has had experience in three countries—Canada, the United States and England—has given it as his opinion that there are more adenoid children to the acre in England than anywhere else in the world. My experience is that a majority of cases of sinusitis in children, just as are a majority of cases of bronchial infection and, I am almost inclined to think, also a majority of cases of chronic gastric catarrh, are due to infection of the adenoid mass. I do not think that every mass of adenoid tissue is dangerous. Quite the contrary. I am making some investigations in an institution with which I am connected and where adenoids and septums and sinuses do not come for treatment, that is, a sanitarium for the tuberculous where I go once a week and examine every patient. Many patients still possess their tonsils and septums, their adenoids are still there and are doing no harm. It is not a mechanical process in the adenoid itself that it becomes a focus of infection. That is the danger where the enemy entrenches itself, and we think it is easier and, if I may use the term, a more sporting proposition to blow up that dugout than to try to drive out the enemy by poison gas. The first line of attack is the adenoid. The only objection is that the young laryngologist is apt to see a fee in an adenoid, sometimes when there is no adenoid there.

DR. I. W. VOORHEES, New York: How does Dr. Oppenheimer examine these patients in his office? Children come accompanied by their mother and are very much afraid. If you have another child or nervous adults waiting outside and they hear a cry or scream, it disrupts the day's work. Another point is the necessity of differentiating between a foreign body and unilateral sinus disease. Just recently a girl, 8 years of age, came to the clinic with a unilateral nasal discharge. I attempted to see if there was any foreign body present but found none. I then examined her under ether and failed to find a foreign body. She was then roentgenographed and the report stated: "Left antrum filled with pus." The child was admitted for opening of the nasointral wall, but unfortunately the admission slip was lost and a tonsillectomy and an adenectomy were reported done instead. The mother came back three days later and said that four years ago the tonsils had been removed. I examined the child and found signs of an old successful tonsillectomy. She still has empyema of the antrum and the mother will allow nothing to be done.

DR. G. W. MCKENZIE, Philadelphia: I understood Dr. Oppenheimer to say that the sinus contained no mucous glands. I question that, because I have done a lot of study on that and my impression is that the sinuses do contain mucous glands, and that there are mucus secreting cells.

DR. LEE W. DEAN, Iowa City, Iowa: In connection with disease of the nasal sinuses in children, it seems to me there is one thing that is axiomatic, and that is the point made by Sir St. Clair Thomson, that the first treatment of sinus disease in children or infants is the eradication of the diseased adenoid tissue in the nasopharynx, which is usually the source of infection. We have now a series of from 75 to 100 cases of sinus disease in infants and children under 12 years of age, where four out of five have been completely cured, so far as the nasal sinus disease is concerned, by the removal of the diseased adenoid tissue in the nasopharynx. The investigation was made in this way. These patients were examined, a diagnosis was made, and then the diseased adenoid tissue was removed. No other treatment was given. The patients left our service and in four or five weeks came again for examination. We found that four out of five of these young children were well, so far as the nasal sinus disease was concerned. When we found that the fifth child did not get well, we resorted to other measures. Investigating the bacteriology of our sinus cases in infants and young children, we found that in eleven out of twelve cases in which there was an arthritis the hemolytic streptococcus was in the sinus, while in those cases in which there was no marked systemic lesion the hemolytic streptococcus was found in only 4 or 6 per cent. of the cases. In the twelve cases with arthritis, the tonsils and adenoids had been removed months before the cases were investigated. Following treatment of the sinuses which were affected marked improvement of the arthritis resulted in every case.

DR. SEYMOUR OPPENHEIMER, New York: In a paper read in New York Dr. Dean brought out particularly the relationship of accessory sinus disease to general systemic manifestations. It has been his experience, as well as my own, that in any number of cases that have been referred to us from the pediatric department or from the general practitioner for determination of where the focus was which was causing the arthritis or other manifestation, that by very careful observation we were able to localize and cure the systemic manifestation after having determined that the focus was in the nasal accessory cavities. Dr. Dean called attention to the fact that in some instances it is not necessary to attack these cavities surgically; however, the simple removal of a mass of lymphoid tissue may be sufficient to allow the proper drainage. I also want to refer to a method mentioned in the chairman's paper, that is, the investigation of these cases while the child is under anesthesia when it is being operated on for diseased adenoids and tonsils. That is the time to puncture the antrum and irrigate it. Dr. Voorhees spoke of the difficulty of examination. I grant that it is extremely difficult in children, but there are methods which can be employed. First of all we must estimate something as to the general appearance of the mucous membrane of the

nose. I have had constructed a very thin bladed speculum of the Killian type which I am able to introduce into the nose and frequently I am able to illuminate the regions that otherwise are not visible. The use of the nasopharyngoscope is most valuable, plus the employment of suction methods in withdrawing secretions. It is not unusual, instead of finding a nose full to find no evidence of secretion; but after the employment of suction methods the secretion is profuse. Sir St. Clair Thomson referred to the fact that the young laryngologist saw in the adenoids a fee. That is quite correct. I have seen a number of children, both in private and hospital practice, where on inspection of the throat a large mass of mucopus was seen dropping down from the nasopharynx. We may jump to the conclusion that the child has a mass of lymphoid tissue, but the history in some cases is that the child has been operated on already. In some instances the secretions may come from an infected sphenoid cavity, and, as I stated, it has been a source of surprise to me how frequently we have been able to demonstrate pus coming directly from the posterior ethmoid cells and from the sphenoid cavity, and in several cases we have been able to show it coming from the ostium of the sphenoid cavity. Any excessive temperature elevation in a child should always call attention to the nasal accessory sinuses.

Dr. Kerley asked what is the symptom complex of chronic sinusitis. I might reply to that by saying, the intranasal finding of purulent discharge. The other general systemic manifestations, such as aching, temperature elevation and a general lack of well being must be considered, but a good diagnosis is practically established by finding a mucopurulent discharge from the nose. It must be borne in mind that a mucopurulent discharge from the nose does not come from the nasal mucosa *per se*, but that every child recovering from scarlet fever or measles has evidence of a mucopurulent discharge from the nose and that is coming from the nasal accessory cavities.

THE ANALYSIS OF HUMAN MILK

TECHNIC OF OBTAINING SAMPLES AND INTERPRETATION OF RESULTS *

FRITZ B. TALBOT, M.D.

BOSTON

The increased interest in breast feeding, which has been the result of recent articles both by pediatricians and by those interested in public health, has again turned the attention of clinicians to the chemical composition of human milk. It is in place at this time, therefore, to draw attention to mistakes which may be made in obtaining the specimens for chemical analysis, the method of analysis, and the interpretation of reports sent by the chemist. Human milk has often been sent to the chemical laboratory for analysis when a baby is sick, and a report returned giving the percentage of fat, lactose and protein. In many instances the practitioner has not been sufficiently familiar with the normal composition of human milk, and its variations under normal conditions, to interpret from the results of the examination whether the milk is abnormal or not; and because of this ignorance many babies have been deprived of their mother's milk when the milk has been normal. It should be a rule, therefore, that an infant should not be weaned because of the analysis of the milk until it has been proved, first, that the milk is harmful to the infant, and secondly, that its composition is abnormal. The composition cannot be said to be abnormal until it is found to be

* From the Children's Medical Department of the Massachusetts General Hospital.

* Read before the Section on Diseases of Children at the Seventieth Annual Session of the American Medical Association, Atlantic City, N. J., June, 1915.

outside the limits of the normal variations of human milk. As will be shown later, the variations of human milk have much wider limits than were previously taught.

The second source of error is the method of obtaining the sample for examination. In order that it shall represent the true analysis of human milk, it must be obtained in one of two ways: First, all the milk should be drawn or expressed from one breast and sent either in bulk or in mixed sample to the chemist. The difficulty with this procedure is to know whether all the milk has been obtained or not. The only way to control this would be to spend the preceding twenty-four hours weighing the baby before and after each nursing to determine how many ounces of milk are taken on the average. When this is known, it can be estimated whether the entire amount of milk has been obtained in the sample sent for analysis. The second method is much simpler in that it only requires the nurse to obtain 1 ounce of milk before nursing and 1 ounce after nursing. These two ounces may be analyzed separately or mixed, but if analyzed separately, they must be averaged.

This complicated procedure is necessary since the percentage of fat is much lower at the beginning than at the end of nursing, the difference occasionally being as much as 10 per cent. The percentage of lactose also changes, although to a less marked degree, being higher at the commencement of a single nursing than it is at the end. The difference in protein is less pronounced and will hardly lead to error. Because of these wide variations it may be seen how easily a wrong interpretation may be made.

The time of day that the milk is drawn also has an influence on the composition of the milk. These figures, which show that there is a difference in the percentage of fat at different times of day, will be reported in another place by Dr. Denis and myself. The highest percentages come at noon or in the afternoon, and sometimes are so high that, if taken alone, they would be considered pathologic. The best time to take a sample of milk for analysis which will give the most characteristic figures is 9 or 10 o'clock in the morning.

The following is an example of how a physician may be led astray by the analysis of breast milk which was obtained in the wrong manner: A sample of 1 ounce was obtained before nursing from a mother whose baby had failed to gain for one week and seemed uncomfortable. The analysis of this sample was: Fat, 1.5 per cent.; lactose, 7.7 per cent.; protein, 1.18 per cent. If these figures are compared with those given in most books as normal figures, namely, fat, 4 per cent.; lactose, 7 per cent.; protein, 1.5 per cent., the sample obtained would prove to be very weak and would explain why the baby was not gaining. I venture to say that in many instances such an analysis would be interpreted as sufficient reason for weaning the infant. This was not done in this case, however, because the milk, when obtained in the correct manner, proved to be a perfectly normal milk. Samples obtained later from the same patient, both before and after nursing, when mixed, contained: fat, 4.05 per cent.; lactose, 7.5 per cent.; protein, 1.16 per cent., which is a perfectly normal human milk. If the first sample had been obtained immediately after nursing, instead of before nursing, the composition would have been: fat, 6.6 per cent.; lactose, 7.4 per cent.; protein, 1.13 per cent., and the milk would have been

said to be too rich and, therefore, indigestible. It is clear, therefore, that breast milk procured for chemical analysis must be taken in one of the two ways outlined above.

Although the method of collecting samples of breast milk is of great importance, the methods of analysis are of equal importance. To inaccurate methods of analysis are due mistakes which are responsible for depriving the baby of its mother's milk. The usual method of analysis used by clinicians and many laboratories is somewhat as follows: First, the fat is determined by the Babcock method, which is sufficiently accurate for all practical purposes; the proportion of sugar is assumed to be so nearly constant that it is set at 7 per cent., and the protein is obtained by subtracting the assumed and known constituents from the solids. Such a method is extremely inaccurate because there is a normal variation of from 6 to 8 per cent. in the lactose content of normal human milk. This variation, of course, reflects on the percentage of protein found in the answer and gives incorrect results. The following analysis was given to me from a case which had a classical textbook history of protein indigestion: fat, 2 per cent.; lactose, 7 per cent.; protein, 4 per cent. Such a milk, if correctly obtained and accurately analyzed, is very abnormal. The symptoms were loss of weight, vomiting, and watery stools containing curds. The analysis of the milk seemed to explain these symptoms and to warrant weaning the baby. On close questioning, however, it was found that the sample of milk was taken from the mother before the baby had nursed because it was more easily obtained at that time. Since there was doubt also as to whether it represented the true chemical analysis, another set of samples were taken correctly, 1 ounce before nursing and 1 ounce after nursing, both of which were mixed and analyzed by Dr. Denis. The fat was determined by the Babcock method, the protein by the Kjeldahl, and the lactose by the Folin-Denis titration method.¹ Its true composition was found to be: fat, 4.35 per cent.; lactose, 7.08 per cent., and protein, 1.75 per cent. This analysis, although slightly richer in protein than the average, was within normal limits for the age. The baby was therefore, not weaned and the symptoms of indigestion were found to be due to other causes. After these causes were removed, the baby did well on the breast.

It is necessary, therefore, both to have the sample of milk obtained in the proper manner, and to have it analyzed by accurate methods before deciding that a single analysis justifies weaning the infant and depriving it of its mother's milk.

In what way can the analysis of human milk help one clinically? The analysis of human milk is of value only when the physician understands its normal variations. Unfortunately, most of us are more interested in the pathologic than in the normal or the physiologic; and when we have to decide whether a given sample is pathologic or not, we are in consequence unable to answer the question. Pathologic chemical variations in human milk are less common than the textbooks lead us to suppose. In the majority of instances the symptoms and not the gross chemical composition of the milk decide for or against weaning. In the following case, the analysis of the milk probably explained the baby's symptoms of indigestion: The baby was having a

1. Folin and Denis. *J. Biol. Chem.*, 33:531 (March) 1918.

great deal of gas and distress, crying most of the day, and passing six green, irritating stools a day which, under the microscope, were seen to contain considerable fat. The mother had considerable gas in the bowels. The analysis showed: fat, 1.4 per cent.; lactose, 8 per cent., and protein, 1.07 per cent. Although no single component was excessively high, the relative proportions of the fat, lactose and protein were abnormal. In this instance after weaning, the baby straightened out on a simple formula of cow's milk.

In another instance a baby was being fed by a wet-nurse who also gave her own baby the breast after the foster-baby received what it needed. It was noticed that although the wet-nurse's baby gained rapidly, it was uncomfortable and a good part of the time had undigested stools. As time went on the foster-baby did not receive enough milk and was given all of the wet-nurse's milk. It then commenced to have indigestion, and it was found on analysis that the additional milk, namely, the end of the milk of the nursing, contained 8 per cent fat. After a wet-nurse with poorer milk was obtained, there were no symptoms of indigestion, and the baby gained weight in a normal manner.

SUMMARY

1. Mixed samples of milk taken before and after nursing, or the entire amount of one breast, must be taken to obtain a characteristic sample of milk for analysis. It should be drawn at 9 or 10 a. m.

2. Accurate methods of chemical analysis must be used. Clinical laboratory tests cannot be depended on because of their inaccuracies.

311 Beacon Street.

ABSTRACT OF DISCUSSION

Dr. JOHN FOOTE, Washington: I think all the great pediatricists have written about the necessity of milk examination. Soranus of Ephesus was the first. He described the thumb-nail test in the second century, A. D. Breast milk varies depending on when the milk is taken, whether at the beginning, the middle or the end of the nursing, and the quality of the milk often depends on the time of day or whether it is taken from one breast or the other, so the matter of making a milk analysis involves many considerations. This was pointed out clearly by Dr. Abt in a splendid monograph a few years ago. The thumb-nail test of Soranus was quite as accurate as some of our modern lactometer estimations of the quality of breast milk derived from a single sample.

Dr. JAMES D. LOWE, Jacksonville: I am convinced that the routine examination of breast milk as commonly practiced with a lactometer more often leads us astray than not. A mother may state that her milk is thin and bluish in appearance and she submits a specimen for examination. We may find that this milk is deficient in fat, and apparently is not a milk on which the baby will thrive; and yet the baby is thriving and taking on weight. Too often we base our estimate on examination of a given specimen of milk. As Dr. Foote has said, the milk in the morning will differ very materially from an afternoon specimen. If the baby is nursing every two or three hours, the milk carries materially more fat than if the baby is nursing every four hours. I merely wish to make the point that unless an examination is made properly and the milk is selected from at least two or three specimens in the course of the day, the routine examination of milk as performed by the average physician will often lead to erroneous conclusions.

Dr. FRIZ B. TAYLOR, Boston: The appearance of the milk really does not tell you anything. We have seen milks that have been very yellow, looked very rich, and yet they have had only 0.9 per cent of fat in them.

ANOMALIES OF TUBERCULOSIS IN THE HIGHLANDS OF COLOMBIA

A NEW DIAGNOSTIC SIGN IN INCIPIENT CASES

JORGE VARGAS S., M.D.

Professor of the General Pathologic Clinic, National University of Colombia

NEW YORK

Physicians of the early part of this century observed a curious evolution of tuberculosis in the great Colombian Highlands. These highlands have an elevation of about 11,800 feet above sea level, and are inhabited by an Indo-Spanish race which numbers very few Indians and many pure descendants of the conquerors. The highlands have an average temperature of from 14 to 16 C. (or 57.2 to 60.8 F.), with an inexhaustible fertility, and are not very thickly populated. Both men and animals progress admirably in this region, notwithstanding deficient hygienic conditions inherited from our Castilian fathers.

I wish to describe the invasion of tuberculosis in these places, which a few years ago were almost free of the Koch bacillus. Today the region is infested with this terrible malady, but with pathologic peculiarities different from what prevails in the temperate zone.

Immunity to tuberculosis is produced by the constant production of antibodies by lymph nodes or other tuberculous tissues. In the highlands of Colombia, certain forms of tuberculosis are most common because the race does not possess immunity to tuberculosis in any degree. The study of these problems is to me of the greatest importance. In the years from 1896 to 1899, I was shown in the clinic of my teacher, Dr. Josue Gomez, in the Hospital de Caridad of Bogota (Charity Hospital), as a pathologic rarity, one or two cases of pulmonary tuberculosis. On the other hand, there were frequent cases diagnosed as tuberculous peritonitis. Numerous necropsies demonstrated the truth of his assertions. Dr. Gomez attributed this phenomenon to various causes. I believe that it was tuberculosis of the mesenteric lymphatics in men who did not have ancestral immunity. This made the invasion of the tuberculosis more rapid so that the action of the antibodies did not stop the rapid peritoneal invasion. Probably, then, the lungs were kept almost immune, the mesenteric ganglions being the place selected by the first tuberculous invasion. The invasion in these organs not immune *per continuitatem* occurred with a rapidity which did not permit the development of antibodies.

During the last four years I have served as professor in the same clinic and have observed hundreds of such cases. There were three things that called my attention especially to the curious nature of the disease in the highlands of Bogota: the rapid cavity formation, the milary forms, and the tuberculous meningitis.

N. N., a man from the country, aged 24, had vomited blood two months before admission, while at his farm, without feeling previously ill. He felt better a few days later, continued his work at the farm, and having vomited blood again forty days afterward, went to Bogota and took a bed in the Hospital de Caridad.

While making the morning rounds, my intern and my chief head of the clinic showed me that case as gastric hemorrhage with vomiting. The man had powerful muscles and a perfect frame, with not a single degenerative stigma. He was a beautiful example of that hardened and healthy type of our

country. On examining him, simple percussion revealed to me the existence of a cavity larger than a dove's egg in the apex of the left lung. The auscultation confirmed my diagnosis. There was nothing else; not an enlarged lymph node; not even a strange noise besides the cavity phenomenon. Based on previous cases observed in my clinic I gave a fatal prognosis. In fact, ten or twelve days later my patient died in a hemoptysis, and the necropsy revealed, as the only tuberculous lesion, the cavity previously diagnosed. In this case, as in eight or ten others, the man was free from hereditary tuberculosis, not having in any other part of his body a tuberculous lesion that might have produced anti-tuberculins.

Tuberculous meningitis also belongs to the not uncommon form of acute tuberculosis generally occurring in the sick—more often in women—while convalescing from great hyperpyrexia, principally from typhoid fever. It is not unusual, observing the cases attentively, to find that the bed next to the meningitis patient is occupied by a tuberculous patient, although on examining the meningitis patient no tuberculosis has been found. Here is new ground, not previously immune, in which, as in the case of a child, the malady takes its most virulent form.

Miliary tuberculosis adopts forms similar to those already mentioned. I was able to observe its frequency after severe hemorrhages in patients not previously subject to tuberculosis.

There are, however, numerous cases of chronic pulmonary tuberculosis. A very curious phenomenon is the clear diversity in pulmonary tuberculosis contracted in the highlands and that contracted in sea level regions. Even if there is no morphologic diversity between the bacilli of one and the other, the clinical evolution of the disease is very different.

Native and foreign men afflicted with tuberculosis who come to the highlands react marvelously to the climate and well-directed treatment. Having been during several years physician for a corporation that imported into the country numerous tuberculous patients, and which took great care in their treatment of them, I had the advantage of seeing some remarkable cures. Only the tuberculous patients with cavities who are so unfortunate (as many are) as to be subject to arterial hypertension die rapidly with hemoptysis.

On the other hand, persons acquiring tuberculosis in the highlands take a slow and sluggish reaction to all treatment. Being acclimated, these patients do not benefit from the advantages of the climate.

A NEW SIGN FOR THE EARLY DIAGNOSIS OF INCIPIENT PULMONARY TUBERCULOSIS

The new sign which I describe has been found in 169 cases of incipient pulmonary tuberculosis. It consists of the reinforcement of the whispered voice in the vertex of the affected lung. This sign appears before the disease reveals itself by any other symptom, either auscultatory or percussional, before respiratory inversion and impairment in the supraspinal triangle of the affected side, which the classics consider as first signs of the malady, appear. A stethoscope and a little practice are enough to find it. The mechanism of the sign is very simple: it might be said that it is the same as the respiratory inversion, and that, examining not the respiratory noise, but the whispered voice, the physician resorts to a trick which allows him to confirm the beginning of the tuberculous process, in a period before the appearance of the principal respiratory inversion.

It is well known that to auscultation, inspiration is noisy and expiration silent. The murmur is produced, not only by the expanding of the pulmonary vesicles, but because each column of air breaking in the flute-like point which forms each bronchial subdivision has to produce a musical sound. This sound is helped also because the column of air subdivides itself in the thick and narrow tubes. The normal exhaling, however, is silent. Now the respiration of a person at rest, who breathes with the mouth open (as in the position of auscultation) and heard near the mouth, presents a phenomenon quite opposite: the exhaling is more noisy than the inhaling. This exhaling murmur is produced in the larynx and pharynx, these organs being the first obstacles that the outcoming column of air finds in which it can produce a musical sound. We see, then, that almost all exhaling reinforcement that is found in auscultation is originated in the larynx, the trachea, and the thick bronchial tubes. The ear that auscults hears them, thanks to the fact that they pass through pulmonary tissues more dense which allow sounds to pass better.

Laënnec showed that the first period of tuberculosis is characterized by a peribronchitis; that is to say, an infiltration of the interstitial peribronchial tissues. This sign is a physical phenomenon. The interstitial peribronchial inflammation increases the density of the lung, and owing to the easy transmission of sound by dense tissues, the larynx and tracheobronchial noises are transmitted in a better way to the ear that auscults, through a tissue of greater density. This explains the respiratory inversion, that is, the reinforcement of the expiration.

When the peribronchial injury is not sufficiently extensive; when the interstitial tissues of the lung have not yet increased enough to conduct with clearness to the ear that auscultates the tracheobronchial noise, it is sufficient to make the patient repeat in a low voice in each expiration a word rich in consonants. In an instant the ear will perceive the great difference that exists, in the case of incipient tuberculosis, between the healthy and the affected side. With a stethoscope carefully applied to the ear, isolating outside noises, a very muffled murmur is perceived, at most, from the healthy side, while from the affected side each syllable is distinctly heard, with such force that it reaches sometimes the degree of whispered pectoriloquy.

I have followed the progress of 169 tuberculous patients from the beginning of the malady; in many of them before the appearance of the slightest symptom. Always, sooner or later, this sign appeared before the respiratory reinforcement and other signs that, associated, did not leave doubt for the diagnosis.

Naturally, in cases in which there already exists respiratory inversion, the sign of the reinforcement of the whispered voice is much more accentuated, getting to be, sometimes, almost pectoriloquy. This sign should not be confused with whispered pectoriloquy, which may accompany tuberculous pneumonia of the apex of the lung, which has an acute progress, with blowing and other signs. The cavities are accompanied also by tympany to percussion. The Niess sign, consisting of whispered pectoriloquy in the space situated between the inside edge of the scapula and the columnar vertebrae, is found also in bronchial adenopathy. Its cause is the transmission of the tracheobronchial breath through the hypertrophic lymphatic

masses. It has nothing to do, therefore, with that which I have described in this study.

As counter control of the sign of the reenforcement of the whispered voice, I had 140 convalescing and debilitated patients (with uncinariasis, anemia, chlorosis, etc.) under observation, who did not present the sign.

The sign described appears at the beginning of the tuberculous lung process, when the roentgen rays do not even give a distinct shadow and when there is not yet any other sign either auscultatory or percussional. Moreover, one may easily become accustomed to finding it.

CLINICAL DIAGNOSIS AS COMPARED WITH NECROPSY FINDINGS

IN SIX HUNDRED CASES*

HOWARD T. KARSNER, M.D.

LEONARD ROTHSCCHILD, M.D.

AND

E. S. CRUMP, M.D.

CLEVELAND

The greatest strides in the wonderful advances of modern clinical medicine have been made by virtue of investigations in chemistry and in physics, in some instances advances with which it has been impossible for pathologic anatomy and histology to keep pace. On the other hand, there are numerous well established conceptions in pathologic anatomy from which the clinical diagnosis must depart, the latter naming the condition in a fashion descriptive of its pathologic anatomy. Not infrequently, methods of functional diagnosis have been widely applied in the clinics after having been verified at the necropsy table in only a limited number of instances, a fact only too well known by critical readers of recent medical literature.

It is not our intention to underestimate the value of clinical investigation, nor, on the other hand, to place too great a valuation on what may be learned from the post-mortem study of patients, but to attempt to reemphasize the fact that in spite of the chemist's investigations in a case, the visualizing by roentgenograms of internal changes and the study of cardiac activity by the polygraph and the electrocardiograph, as well as study by other precise methods, the vast majority of clinical diagnoses can be accepted or rejected only on the basis of naked eye, microscopic, chemical and bacteriologic examination of the body after death. Such control of diagnosis should serve as a stimulus rather than as a deterrent to rendering more exact the study of the living patient, and it is with the hope of furnishing such a stimulus that we present our case records.

Richard Cabot's widely read article on "Diagnostic Pitfalls Identified During a Study of Three Thousand Autopsies" pointed out in very striking manner the factor of error in a list of twenty-eight special lesions and diseases. It occasioned resentment on the part of certain clinicians accustomed to the ex cathedra method of diagnosis, but in many others served to stimulate

greater precision in methods of examination. It has also been used by unscrupulous persons to discredit the practice of medicine. Scientific medicine, however, is too firmly established to fear any such attacks and can only profit by the open-mindedness and critical self-examination of occasional reviews, such as that of Cabot.

By fine examinations and strictest interpretations, the pathologic anatomist might demonstrate, perhaps, a greater percentage of error on the part of clinical diagnosis than is indicated by Cabot, particularly errors of omission, were he to include minor degrees of arteriosclerosis, slight sclerosis of heart valves, cloudy swelling of parenchymatous viscera, agonal congestion and other similar lesions; but fairness demands that he include only such apparent lesions as might reasonably be expected to present definite signs and symptoms in life. Such an attitude should be met in like spirit by the clinician, and studies such as the present one be accepted in the light of attempted friendly cooperation rather than in that of the bitter and destructive criticism all too frequently exhibited at the necropsy table.

Our studies are of 600 cases equally divided between two large hospitals in Cleveland. Our series is too small to permit of the same division as made by Cabot and still reach satisfactory percentages in some of the less frequent diseases. We have therefore decided to classify by organs and systems rather than by special lesions. There were, however, certain marked errors of diagnosis that defy any such classification. These we have classified as gross errors, and we have not included any instances in which the clinical diagnosis, even though markedly in error, was of the same organ found diseased at necropsy. We have included, however, certain very obvious errors of omission. This group numbers fifty of the 600 cases, or 8 per cent. As for the hospitals, in one there was 6 per cent. of such errors, and in the other, 10 per cent. A few examples serving to illustrate the type of error included in this group will be found in Table I.

TABLE I.—ILLUSTRATIVE EXAMPLES OF THE TYPE OF
"ERROR OF OMISSION" IN CLINICAL DIAGNOSIS

Clinical Diagnosis	Pathologic Diagnosis
Lobar pneumonia	Cerebral tumor; no pneumonia
Acute endocarditis	Acute peritonitis from ruptured pus-tube; no endocarditis
Lobar pneumonia	Epithelioma of larynx; tuberculosis right upper lobe; no pneumonia
Typhoid fever	Lobar pneumonia
Carcinoma of stomach	Lobar pneumonia; no stomach lesion
Cardiovascular disease	Carcinoma of stomach
Cerebrospinal syphilis	Acute psychonephritis
Acute leukoderm	Fracture of skull
Tuberculous meningitis	Bronchopneumonia
Aneurysm of descending aorta	Atrophic cirrhosis; rupture esophageal vein
Cirrhosis of liver	Lobar pneumonia; cloudy swelling of liver
Carcinoma of stomach	Pulmonary tuberculosis; amyloid liver and spleen; no lesion of stomach

We have classified as "minor errors" those in which the affected organ was properly diagnosed, thus including here the errors of commission. In addition, this group has been made to include the failure to observe lesions of the special organs. Many of these errors are not so serious as to justify inclusion in the "gross errors;" but in order to make the figures more accurate, it is necessary to include with each organ cases which also have been classified above as gross errors. We have compared the number of correct diagnoses to the total number of cases diagnosed, and have thus estimated the percentage of error of commission. It is to

*From the Department of Pathology, Western Reserve University School of Medicine.

*Read before the Section on Pathology and Physiology at the Seventeenth Annual Session of the American Medical Association, Atlantic City, N. J., June, 1919.

1. Cabot, R. C.: Diagnostic Pitfalls Identified During a Study of Three Thousand Autopsies, J. A. M. A., 59: 2295 (Dec. 28) 1912.

be presumed, however, that if a patient is admitted to a hospital, a complete examination is made, so that the failure to discover a distinct lesion must be looked on as affecting the statistics of diagnosis as applied to the particular organ under discussion. We have included only those organs and parts of the body in which diagnoses have been made and pathologic lesions found in sufficient number to justify the percentage estimate of success. It is invidious to make comparisons between two hospitals in the same community, the staffs of which are made up of different visitants and house officers; but it is of interest to note that the percentage of error was practically the same in each institution, except in the case of heart and pericardial lesions. In respect to these, one hospital had a 74 per cent. error of commission, and a total error of 80 per cent.; whereas the other had a 41 per cent. error of commission and a total error of 52 per cent. Table 2 furnishes the data.

TABLE 2.—MINOR ERRORS

Organ or Part of Body	Cases Diagnosed	Correct Diagnoses No.	Correct Diagnoses Per Cent.	Cases Overlooked No.	Chance of Correct Diagnosis Per Cent.
Head and brain	72	43	60	7	54
Heart and pericardium	119	62	52	36	47
Lungs and pleura	174	95	54	77	38
Position of lobar pneumonia	48	25	37	12	31
Liver and biliary tract	30	12	57	17	36
Gastro-intestinal tract	69	36	54	8	49
Nonsuppurative nephropathy	60	46	77	7	34
Blood vessels	36	24	67	21	42
Totals for these organs	625	348	56	192	40

Certain notes in addition to the table are desirable. Most of the errors in the diagnoses of heart lesions were errors in regard to valves affected. The errors of omission in disease of the lungs and pleura do not include terminal pulmonary edema or slight, terminal bronchopneumonias. In regard to lobar pneumonia, the errors formed a sufficient number of the errors of pulmonary diagnosis to justify separate classification. The table does not show the fact that of sixty-eight cases in which the diagnosis was lobar pneumonia, twenty failed to show this disease, most of these cases being those of well marked bronchopneumonias. Certain errors of diagnosis in the gastro-intestinal tract are of interest. There were twelve cases in which the clinical diagnosis was carcinoma of the stomach, of which ten were correct; of the others, one was a case of pulmonary tuberculosis, and the second, one of peritoneal tuberculosis. Six cases of typhoid fever were correctly diagnosed and three incorrectly diagnosed, two being cases of generalized miliary tuberculosis, and one a streptococcus septicemia. In regard to the large number of cases of nonsuppurative nephritis overlooked, it is but fair to state that more than half of these were cases of chronic interstitial nephritis. In only six cases of other renal lesions were diagnoses made. Four were correct, namely, acute pyelonephritis, perinephric abscess, infected infarcts and tuberculous nephritis. There were, however, fourteen cases overlooked, all suppurative except one case of nephrolithiasis, so that the percentage of correct diagnosis in this small group is eleven. In the diseases of the vascular system there were not included as overlooked the many cases in which there was a minor degree of intimal sclerosis of the aorta.

If the total number of cases is added to the number of cases overlooked, the sum exceeds 600, the figure previously given as the total of the number of cases.

This is explainable by the fact that there were combined lesions in numerous cases. This factor is more real than apparent, because numerous miscellaneous cases have been used simply as a percentage basis for ascertaining gross errors. Thus, the figures tabulated in Table 2 apply only to the organs and systems included in the table.

The data furnished refer to clinical histories filed in the two hospitals over a period of several years; and while they cannot be regarded as indicating the diagnostic ability of the visiting chiefs, they do represent the average or mean diagnostic ability of the clinics of these men, as indicated by the permanent records of their cases. The pathologist sees and feels things directly, whereas the clinician must, in many instances, interpret phenomena observed only indirectly; but both have the same facilities for making records, and it is fair to presume that in a given institution the records of clinic and laboratory are subject to much the same factor of completeness or incompleteness.

If clinical diagnosis in a large community, well and favorably known for its medical investigation and teaching, is subject to an 8 per cent. factor of gross error and a 60 per cent. factor of minor error, it is reasonable to suppose that similar chances of error exist in less favored communities. This cannot be interpreted as a failure on the part of the clinician to give his cases proper attention and therapy, for many of the minor errors disclosed had no influence whatever on the treatment of the case or its outcome. To differentiate all the cases in which the errors in diagnosis would influence the outcome presupposes a knowledge of the intricacies of natural adaptation to disease which science at present does not possess.

The improvement of clinical medicine depends, however, on increasing accuracy of diagnosis, from which a more rational therapy may be adduced. The exact benefit of improvement in the diagnosis and in the treatment of the diseases of man to his productive labor can be estimated only from morbidity statistics which have never been accurately tabulated for any large group of people. The improvement must be along lines of more exact clinical study, and can be properly controlled almost solely by recourse to the postmortem examination of carefully studied patients. The service of such examinations is not only to the medical profession but directly to the public, as has been emphasized by several writers, most notably, L. B. Wilson,² who points out their importance to vital statistics and to studies of heredity. The value of these to the public is great. The actuarial calculations of life insurance companies are based on vital statistics, based largely, in turn, on clinical diagnoses. Any constant error of clinical diagnosis is therefore reflected in such figures. If, therefore, the figures were placed on a more accurate basis, a more just charge for life insurance would be established. To these advantages of necropsies is to be added, as pointed out above, the probable increase in public health accruing from greater accuracy of clinical diagnosis. "The education of the medical profession by accurate postmortem diagnoses is a veritable safeguard for the public welfare."³

If the value of the necropsy is so well established, what is American medicine doing to further its own

2. Wilson, L. B.: The Necropsy as a Public Service, *J. A. M. A.* 64: 15-10 (May 8) 1915.

3. The Necropsy Situation in the United States, editorial, *J. A. M. A.* 68: 783 (March 10) 1917.

advancement by control of clinical diagnosis? In the report of a committee of the New York Academy of Medicine in 1914,⁴ it was pointed out that in a selected series of large hospitals in the United States the percentage of necropsies, as compared with the total number of deaths, was one eighth that in Canada, Great Britain, Austria and Germany. At that time, in only two hospitals was the number of necropsies above 40 per cent. of the deaths. According to Winternitz,⁵ this number had increased in 1917 to include eight hospitals of twenty-two answering a questionnaire. He says, "Perhaps the selection of hospitals was fortuitous;" and, when one reads the list of hospitals, it seems that the assumption is correct. In this list of eight hospitals are included the Robert Brigham⁶ and Cincinnati General⁷ hospitals, with, respectively, 70 per cent. for two years and 63 per cent. for one-half year, periods too brief to indicate sustained interest in the matter. These figures indicate a distinct tendency toward improvement, proceeding, however, at a disappointingly slow rate. Indeed, one of the large hospitals in this city, during the year 1918, showed a reduction from an average of 40 per cent. over several years to 18 per cent., whereas the other increased from 13 per cent. to 15 per cent., both being affected in practically the same way by war conditions and the epidemic of respiratory infection.

CONCLUSIONS

Investigations of the cause of this general shortcoming of American medicine in studying the accuracy of clinical diagnosis lead to a variety of explanations and an equal variety of suggestions for improvement. The latter may be thus summarized:

There should be:

1. Education of the public as to the importance of post-mortem examinations to public health.
2. Improvement of legislation: (a) obviation of the necessity for written permission to perform a necropsy, and (b) recognition of the difference between anatomic dissection and the necropsy.
3. Improvement of hospital regulations.
4. Increased development of the interest of physicians in the necropsy.
5. Encouragement of the "selfish interest in postmortems on the part of intelligent relatives of the dead."
6. Assignment, in large hospitals, of certain persons whose special duty it shall be to secure permission for post-mortem examinations.
7. Information given the family as to the conditions disclosed by the necropsy.
8. A request for necropsy in every fatal case in hospital or private practice.
9. Establishment in the hospitals of regular clinical pathologic conferences.

We would suggest, in addition, that the subject is of direct importance to the development of industrial medicine and that those interesting themselves in this subject point out to employers and employees the value to medicine and industry of post-mortem examinations. The suggested alteration of actuarial figures regarding life insurance is of similar importance to the so-called health insurance.

ABSTRACT OF DISCUSSION

DR. FRANCIS CARTER WOOD, New York: It is necessary to be very frank in our discussions and to realize that neither medicine nor surgery is as yet perfect. The public is as well aware of this fact as we are. The only way to improve diagnosis is to follow our cases with the greatest care and to study our practical results and those of others. Failures in diagnosis are often due, not so much to lack of knowledge as to lack of thoroughness and care in examination. Too much reliance is placed on laboratory reports, which are popularly supposed to have an infallibility with which no laboratory man would credit them. One way in which to improve the treatment of patients is to have students in the hospital wards. In teaching them the physician teaches himself. The private practitioner must fall back on reading, on attendance at medical lectures and meetings, and on most careful and thorough study of his patients.

DR. W. CARPENTER MACCARTY, Rochester, Minn.: For a number of years I have been greatly interested in the comparative study of clinical and pathologic diagnosis. In justice to the clinician we must divide all errors into three groups, namely, actual errors, apparent errors and avoided errors. The actual errors are those which might affect the welfare of the patient by virtue of being misleading in so far as therapy is concerned. The apparent errors are usually those in terminology and may not affect the patient. The avoided errors are those in which the diagnosis is guarded by some general descriptive or localizing term. We must work with the clinician and not antagonize him. He must do likewise with the pathologist. I am not saying that Dr. Karsner criticizes him but I feel that his facts may be interpreted as criticism. I am associated with clinicians with whom I attempt always to consider one object, namely the patient. Much of the difficulty of clinicians has arisen from their attempt to utilize detailed pathologic terminology for clinical purposes. Pathology terminology as a means of communication of ideas is inefficient even for pathologists. If we do not change our attitude toward clinicians and patients the pathologic work of clinics will be done by laboratory girls who may be able to meet the emergency technically but who will be short on judgment. Our attitude should not be one of antagonism but one of strenuous attempt to give the patient the proper prognosis. I have lived with clinicians for twelve and one-half years. We have never had an argument and we have never had any trouble. The judgment from the laboratory is the last court as far as diagnosis is concerned. Pathologists throughout the world must take the same attitude. We have much to correct in our own specialty. We must first have our own conceptions of diseases clear and then utilize a simple and accurate code of communication of ideas. There is no uniform terminology in our textbooks. Much of our science is absurd, certainly ambiguous. It is inefficient, not only from a clinical standpoint, but from our own standpoint. We have to correct ourselves or our places will be taken by those not as scientifically trained as we are. We must get into the game of rendering immediate service to patients. The game can be played only by means of team work and by diplomatic constructive analysis of our own faults and those of our colleagues.

DR. E. R. LE COUX, Chicago: We should remember that the post-mortem examination is a measure, for the most part, of things that are rather certain; lobar pneumonia, for example, is definite. When we compare such definite lesions as lobar pneumonia with the conditions that attend clinical diagnosis, it is a little hazardous because of the many varying factors which enter into clinical diagnoses, and one of these to be thought of always is the time element. How long has the patient been under observation? I do not think it is quite fair to any clinician to charge him with an error in diagnosis unless he has had adequate facilities for making a diagnosis including the time. There are many other factors. Dr. Karsner mentioned sclerosis of the heart valves. We all know how common it is to find sclerosis of the front mitral leaflet. It is practically constant in the later years of adult life, but hardly any of such sclerosis deserve a place as diagnosable lesions. I have contented

myself so far, as far as possible, with showing the clinician what is present and avoiding any discussion as to why he did not make a correct diagnosis. Often such failure to comment is as effectual as a long drawn out discussion.

DR. HENRY A. ALBERT, Iowa City, Iowa: There is no doubt in my mind that we should place much more emphasis in the teaching of medical students on the importance of a knowledge of pathology, more especially gross pathology, than we do at present. The correlation of such with the clinical findings can be best brought out at the postmortem table. In this respect we are more fortunately situated than are many others. We are in a small community with a hospital of 500 beds entirely under the control of the hospital staff and practically all patients are clinical cases. About fifteen years ago, only about 25 per cent. of the cases which terminated fatally reached the necropsy table, whereas at the present time, the percentage is about 85. All our clinicians are interested in pathology. The rule at our institution is that necropsy work takes precedence over all other work. The clinicians have agreed to permit necropsies to be given preference, in point of time, to any other work. In case of necessity our clinicians are perfectly willing to give up a surgical or medical clinic, so that they and the students can attend the necropsy. For some years the clinicians and pathologists have compared notes. The students also make both clinical and pathologic examinations and compare the findings. These take place to a certain extent at the time the postmortem examination is made. The clinician is there and the essentials of the clinical history are presented. The pathologic conditions are noted and discussed. After the bacteriologic findings have been noted and microscopic examinations of the tissue specimens have been made by the students, all the pathologic findings are again discussed and the correlation between such and the clinical symptoms is again made. We have found such frank consideration of all of the findings of a given case to be very helpful.

DR. W. M. L. COPLIN, Philadelphia: I would like to ask Dr. Karsner if he could tell whether the errors in diagnosis were in cases used for teaching purposes.

DR. H. E. ROBERTSON, Minneapolis: I am in entire sympathy with Dr. Karsner's object in presenting this paper. However, I do wish to be cautious in allowing those who do not understand fully the difficulties of the practice of medicine to be placed in a position where they can criticize the medical profession by quoting from its own members criticisms which are not fully understood and often out of place. Our profession has many weak spots and we have been rather lax in attempting to correct these. The other day there appeared before our county medical society two laymen whose duty it was to call attention to the lax methods pursued by modern hospitals in the professional care of the patients under their charge. This fact appeared to me to be a very ominous sign and showed that we are in danger of having done for us by outsiders things that we should do ourselves. One point of attack on this problem which seems to me to be very important is on the teaching done in medical schools. In these students our hope must lie for the radical improvement of existing conditions and if we present these high ideals of practice and living properly, without radical revolution but by evolution, we may find many of the present evils corrected in one generation. Socialized medicine in some form or other is almost certain to overtake us. Wise criticism and planning may regulate this to the advantage of the profession as well as that of the public. Nowhere is this wise criticism so important as in the relation between the pathologist and the clinician, and the responsibility of the pathologist is often very great. I am inclined to think that at times, at least, the clinician needs sympathy and instruction rather than publicity.

DR. FRANCIS CARTER WOOD, New York: I think much of what has been said depends on the fact that we are working with an older group of physicians, men who have not the laboratory training of the last ten years. I feel, as Dr. Robertson does, that our educational ideals in the medical schools are not yet high enough in the sense of teaching the men the responsibility which they assume when they under-

take the practice of medicine and the necessity of thorough investigations of individual cases. The reason for much of the slipshod work in diagnosis is that in their desire to take more patients physicians assume more than they can do well. The same thing is seen in the hospitals, where a man will see a large number of patients very superficially, but is unable or unwilling to spend a great deal of time with any one patient.

DR. H. T. KARSNER, Cleveland: The most serious criticism of the aims of this paper is that made by Dr. Robertson. I feel that nothing appears in the paper that should not be seen by the profession or the public and maintain that an intelligent medical or lay public can understand that the inaccuracy of clinical diagnosis is not a reflection on the medical profession but rather an indication of the need for improvement. Such improvement can only be attained through cooperation based on complete understanding of the situation. Concealment of these facts can lead only to regression. Dr. Robertson suggests that the necropsy can be employed as a means of indicating a man's diagnostic ability, but I feel that it reveals rather the limitations of diagnostic methods. In hospitals where consultations are freely employed the index is one of staff rather than individual. In reply to Dr. Coplin, most of the cases were used for teaching purposes both before and after death. Between the third and fourth year of medicine in Western Reserve University, there is only a three weeks' vacation period so that the clinical material is used throughout the year. In addition, the fourth year students, as clinical clerks, attend the clinical-pathologic conferences on the cases that come to necropsy. In reply to Dr. Albert, we hold clinical-pathologic conferences in both the hospitals used in this study, and in the fourth semester of the year we also hold similar conferences for the entire second and third year classes, in which the third year students present the clinical features and the second year students the pathologic features of the cases under discussion. In all these conferences any errors disclosed are traced as far as possible to the source with the idea of evaluating clinical and laboratory diagnostic methods. In reply to Dr. Le Count, we did not include cases which were in the hospital too short a time to permit reasonable clinical examination, and as stated in the paper did not include minor or agonal pathologic lesions which the clinician could not be expected to have diagnosed. I quite agree with Dr. MacCarty that there should be a standardized nomenclature in pathology but cannot agree that his device brings us materially nearer a solution of the problem. Pathology alone cannot settle the matter because the terms used are in most instances common to the entire field of medicine. We, as pathologists, have no quarrel with the clinicians. On the contrary, we stand in need of closest cooperation. Any disagreement that may occur are rather a battle between progress and reaction than a conflict between pathologists and clinicians. By our ability to see things directly as they occur in the body rather than through layers of skin, fat and other structures, we are in a position to verify or correct diagnoses made at the bedside. This difference should always be recognized and lead to harmonious discussion rather than acrimonious debate.

Vaccine Against Cancer.—Professor Kappin of the University of Nantes is director of the Pasteur Institute, and as early as 1886 he called attention to a micro-organism which he found constantly in cancer and has continued to find it since, although his research has been fragmentary. He has been recently experimenting with a vaccine made from this micro-organism and reports in the *Bulletin médical* of July 19, 1919, three patients with inoperable cancer treated with it. He considers the results encouraging, although his material was so small and not demonstrative. He gives illustrations of the micro-organism as seen in an alveolar cancer, hoping others will carry on the research more thoroughly. His previous communications were published in the *Gazette médicale de Nantes* and in the *Comptes rendus des séances et mémoires de la Société de biologie*, Dec. 10, 1887.

EXPERIENCES WITH DUODENAL FEEDING AT U. S. ARMY GENERAL HOSPITAL NO. 41*

JACOB BUCKSTEIN, B.S., M.D. (NEW YORK)

First Lieutenant, M. C. U. S. Army

FOX HILLS, STATEN ISLAND, N. Y.

At General Hospital No. 41, we have treated gastric patients returned to this country from duty overseas as well as patients from among the enlisted members of the detachment. Practically all of these patients had been under dietetic treatment before reaching our ward, but the symptoms were continuing in unabated form. It occurred to us that, rather than again subject the patients to a procedure that had failed to produce improvement, we would have recourse to Einhorn's duodenal alimentation. The underlying principle appeared to be rational, that through rest of

for as long a time as six weeks or more in the case of a chronic ulcer. We, therefore, had one patient swallow the rubber tube with no bulb attached. In this particular case the end of the tube actually passed through the pylorus into the duodenum (Fig. 1). But every other attempt failed, the tube coiling on itself within the stomach. A weight at the end of the tube seemed quite valuable in facilitating the passage of the tube into the proper place. We could not, however, understand the particular value of the weight once the tube had reached the duodenum, whereas the continued pressure might be a conceivable source of danger. We therefore sewed a bulb on the end of the rubber tube with plain catgut. The tube was swallowed by the patient that evening, and a roentgenogram was taken the following morning which showed the tube in place and the bulb detached and present in a different portion of the intestine. The catgut had been absorbed, permitting the bulb to escape (Fig. 2). Owing to the

Fig. 1 (Case of E. F. L., Pvt., Medical Detachment).—Early typical history of ulcer with positive roentgen finding, blood in the gastric secretion, and a blood stain about 1 inch in length on a string, 21 inches from the teeth. The patient on discharge had gained 15 pounds and had no complaints. The tube was swallowed with no bulb at the end, yet passed into the duodenum without coiling on itself. Other attempts to have a tube pass into the duodenum with no weight at the end failed, for the tube coiling on itself in the stomach.

Fig. 2 (Case of G. C. B., Pvt., Medical Detachment). In this case a bulb was sewed on with plain catgut to the end of the rubber tube. The tube was swallowed the evening and the roentgenogram taken the following morning. As a result of the absorption of the catgut, the bulb became detached from the end of the tube, which had passed into the duodenum.

Fig. 3 (Case of E. A., First Lieut., M. C.).—Owing to the fact that plain catgut absorbed with such rapidity, so that in some cases the bulb became detached while still in the stomach, it was decided to use chromicized catgut. The arrow points to the bulb, which has become freed from the end of the tube to which it was originally sewed. The bulb was recovered from the stool about thirty-six hours after it was swallowed.

the diseased area, by completely excluding it, nature might be given the opportunity of effecting recovery. Our results with this method have been encouraging.

We modified the duodenal tube in a few details. According to its original construction by Einhorn, as also in the modifications by Gross, Palefski and Relbuss, there is a perforated metallic attachment at one end. We attempted to get rid of this metallic end-piece. It is not possible that a metallic weight of that sort might, if left in contact with the soft lining membrane of the duodenum or jejunum over a prolonged period of time, produce an erosion with possible hemorrhage or ulceration. Especially might this occur where it would be desirable to keep the tube in place

rapidly with which plain catgut is absorbed, we have been using chromicized catgut. In the case of another patient we sewed the bulb on with chromicized catgut. The roentgen-ray finding taken eighteen hours after the tube was swallowed is shown in Figure 3. In one case, the lumen of the tube became so occluded that food would not flow through. We, therefore, made several openings at varying distances from the end to minimize this possibility. The duodenal tube, as we use it, consists of 45 inches of thin, readily collapsible rubber tubing with several openings along the side, the openings being about as large as the lumen and located at different intervals for a distance of approximately 11½ inches from the end. Sewed with chromicized catgut to the end of the tube is a small perforated metal bulb, which eventually becomes detached and may be recovered from the stool.

* Read before Hospital Staff, May 27, 1919.

* This work was conducted in the service of Major Frank R. Tomney, chief of staff, and Dr. Samuel M. Frank Harnden.

We have become impressed with the value of the drop method of feeding the patients as originally advocated by Dr. Morgan. Feeding with the syringe as proposed by Einhorn may produce distention, pain and nausea. In one case, it produced cardiac palpitation with flashes of heat; in another case, flashes of heat followed by a feeling of cold, evidences of a possible vasomotor disturbance. In the normal mechanism of alimentation the stomach, which, as one of its functions acts as a reservoir, from time to time forces some of the chyme through the pylorus into the duodenum. In duodenal feeding the stomach as a reservoir is eliminated. The food passes directly into the intestine with its comparatively small lumen.

That an increase in bulk at any one time may cause distention appears probable. Moreover, when feeding is done by the drop method, there is increased opportunity for the material to mix with the secretions and for greater consequent enzymic action.

of glass tubing into which one of the medicine droppers fits, a screw clamp and a container, all arranged as seen in Figure 7. The method is simple, practical and inexpensive. When available, a vacuum bottle as a container may be used to advantage.

As to the localization of the tube, we have found no method so satisfactory as a roentgenogram. Far from being unnecessary or unimportant, as is usually stated, we know of no better way of determining exactly the position of the tube and where the end of it is. Even if all other facts were to prove conclusively that the tube was in the duodenum, we should have no definite clue as to how far the end of the tube reached. Shall we judge by the length of tube swallowed? That is uncertain because the tube may coil on itself (Fig. 4). By injecting a suspension of barium through the open end of the tube by means of a syringe and taking the roentgenogram during the process, we have a complete column of barium outlining the tube. Within fifteen

Fig. 4 (Case of G. C. B., Pvt., M. D.).—An illustration of the fact that the length of tube swallowed gives no certain indication as to where the end is, as the tube may coil on itself.

Fig. 5.—One of the factors that may interfere with the proper flow of fluid through the tube, namely, a kinking of the tube without any actual obstruction.

Fig. 6 (Case of J. L., Corporal Inf.).—This picture, taken twenty four hours after the tube has been swallowed, still shows the bulb attached to the end of the tube. It had been sewed on with chromicized catgut No. 4.

Not only the direct introduction of a bulk of material by the syringe method, but even an increased flow by the drop method may produce discomfort which often can be obviated by regulating the rate of flow and decreasing the number of drops per minute. The rate best suited can be determined only by a study of the individual case. Given slowly, drop by drop, there is less possibility of the food's accumulating in the duodenum and backing up toward the pylorus, thereby perhaps coming in contact with the ulcer we are attempting to treat. This contingency may also be minimized by attention to the patient's position in bed during the period of feeding. Referring to Figure 3, we see that the end of the tube is at the end of the transverse portion of the duodenum. In this case the patient was instructed to lie on his left side during the feeding so as to aid in draining the fluid away from the duodenum and toward the jejunum. Apart from the duodenal tube as described above, the rest of the apparatus we have been using consists of two pieces of rubber tubing, two medicine droppers, a 4-inch piece

minutes the plate is ready for inspection. In the case of a duodenal ulcer, it is important not only that the tube be in the duodenum, but that the end be sufficiently far removed from the diseased area to avoid all possible contact of the food with the ulcer. In one case a roentgenogram showed the end of the tube in the duodenum. It also showed an escape of barium from the part of the tube within the stomach. On removing the tube we found the opening from which the barium had escaped.

After the tube is in place, the following possible occurrences may interfere with the proper flow of fluid through it: The lumen may become occluded. To minimize this possibility several openings were made at varying distances from the end of the tube as described above. Another possibility is a kinking of the tube. This is shown in Figure 5. In this case the food material failed to run through by the drop method. It could, however, be forced through with a syringe. We were able to correct the difficulty by gradually pulling out several inches of the tube until

the food again flowed through with no obstructions. A third factor which may prevent the food from passing through is pylorospasm, the sphincter contracting on the rubber tube. On several occasions in the course of duodenal feeding the fluid failed to pass through. Attempts to force it through with a syringe were equally unavailing. We had the patients swallow some water, and within a few minutes the food again passed through by the drop method without the slightest difficulty. We believe a relaxation of a contracted pyloric sphincter may explain this result.

The material the patient is fed should be fluid, and of such a nature and such bulk as to give him a maximum degree of comfort, and at the same time supply him with a caloric value requisite to maintain his weight, and a sufficient amount of protein to keep him in nitrogen equilibrium. It is an interesting physiologic phenomenon that, fed in this way directly into the intestine, patients are able to retain their weight over

a period of several weeks, during the entire course of the treatment. In maintaining a patient's weight, we have an added factor that is of value in healing the disease.

No definite feeding formula can be laid down. Each case must be studied individually. One must seek that happy combination of proper rate of flow, total bulk, and nature and concentration of food contained therein that will support nutrition with a maximum degree of comfort. An average mixture as we have employed it in our ward may contain 150 c.c. of peptonized milk; 70 gm. of glucose; 2

Fig. 7.—Outfit for duodenal feeding; A, petriolated metal bulb; B, chromized catgut; C, end of duodenal tube, with opening; D, medicine dropper; E, rubber tube; F, glass tube containing medicine dropper; G, rubber tube; H, screw clamp; K, vacuum bottle.

eggs, and 40 gm. of butter. In a patient, weighing approximately 60 kg., who is at rest, such a mixture given three times a day is sufficiently ample to sustain his body requirements.

The length of time the tube is permitted to remain in place must necessarily vary with the individual. To establish a definite period for all cases is to disregard obvious differences in healing power in different persons. This will vary with age, inherent recuperative power, as well as with the chronicity and severity of the lesion. To determine how effective the method of treatment has been, the patient is fed by mouth after a variable period has elapsed, while he is still being fed by the tube. In this way we have some means of judging the extent of recovery. As we find that we can increase the food by mouth, we eliminate one of the feedings by tube. Finally we dispense with duodenal feeding entirely and remove the tube. If we were to

find that pain recurred on feeding by mouth, the tube still being in place, we could continue duodenal alimentation.

CONCLUSION

These points should be emphasized:

1. The importance of a duodenal tube with a weight at one end that is readily detachable shortly after the tube has reached the duodenum, and that has several openings near the end to minimize the possibility of occlusion.
2. The importance of the drop method of feeding.
3. The value of the roentgen ray for localization of the tube.
4. The conviction that we are dealing with a method that is not uncomfortable to the patient, as a rule, when properly handled, that we believe to be rational in its underlying theory, that enables the patient to maintain his nutrition, and that may prove of value in some cases.

ARACHIDIC BRONCHITIS*

CHEVALIER JACKSON, M.D.

AND

WILLIAM H. SPENCER, M.D.

PHILADELPHIA

We have selected the term "arachidic bronchitis" to apply to a special form of bronchitis due to the aspiration of peanut kernels into the lower air passages. It doubtless should be applied also to analogous cases caused by the aspiration of a few other organic substances; but up to the present time relatively few cases caused by other substances have been observed; whereas, with peanut kernels, the cases have been so numerous and the evidence so overwhelming as to demand a place among the list of diseases affecting the bronchi and lungs of children.

There are only three references to "peanut bronchitis" that we have been able to find, one by Chevalier Jackson,¹ another by Ellen J. Patterson,² and a third in the Mütter Lecture for 1917,³ wherein the visible living endoscopic pathology of arachidic bronchitis is discussed under the name peanut bronchitis.

DIAGNOSIS

The resemblance of the symptoms to those of laryngotracheal diphtheria is sometimes most striking, and in a number of cases antitoxin had been administered, though laryngeal smears and cultures had shown no *Bacillus diphtheriae*. There is in all of the cases a varying degree of dyspnea and restlessness which is usually more marked in the younger children. It was noted that the cases of peanut bronchitis show a marked toxemia, which we ascribe to the absorption of toxins from the difficultly expelled lung secretions. This toxemia resembles that seen in the acute infections, and is at times accompanied by a mild delirium. There is a marked difference between this toxic condition produced by the peanut and the purely septic condition which is seen in cases in which there has been

a prolonged sojourn in the bronchus of substances of other than vegetable nature.

A dusky cyanosis is often present, but in the bronchoscopic clinic it has often been noticed that in children who have been fighting for air for a rather prolonged period of time, from any cause, this duski-ness often is superseded by an intense pallor, the result of the excessive heart strain incident to the strenuous efforts of the muscles of respiration. This pallor frequently causes a false sense of security on the part of the attendant, who is accustomed to associate urgent dyspnea with cyanosis; and tracheotomy has often been performed too late, even though the cardinal signs, retraction of the suprasternal and supraclavicular fossae, and of the lower ribs and epigastrium, have been present the while. Distressing cough is a constant symptom; in the older children it is often paroxysmal and associated with the expectoration of a pinkish-gray, thick, tenacious, purulent sputum, which is very difficult to dislodge from the air-passages.

The clinical chart shows an irregular, septic type of temperature elevation; and the heart rate and the respiratory rate are usually higher in proportion than the temperature, as would be expected when we consider the restlessness and the dyspnea present (Fig. 1). The physical signs reveal a generalized diffuse bronchitis, with an accentuation of the signs at the site of the foreign body. The asthmatoïd wheeze⁴ is present in the large majority of the cases. This is a wheezing sound of a dry character, heard by placing the ear at the open mouth of the patient and requesting him to make a forced expiration. The wheeze persists after practically all secretion has been coughed out of the air-passages, and is often so loud as to be audible across the room. The patient rarely loses the voice, a point which may aid in the differentiation from laryngeal diphtheria.

Inspection of the chest will usually reveal a lessened expansion on the side of the foreign body; percussion, an impairment of resonance, and auscultation, a diminution of the intensity or absence of the transmission of the breath sounds and voice sounds in that portion of the lung distal to the foreign body. These signs may be definite enough to warrant a localization of the intruder in a certain bronchus. Loud, bubbling, so-norous and sibilant râles are heard throughout the chest; these are, however, often of greatest intensity over the site of the foreign body. In some of the cases the marked dullness in the lower portion of one side of the chest, together with the absence of breath and voice sounds, has been interpreted as fluid in the pleural sac, and exploratory punctures, and even rib resections, have been made, only to find the pleura normal and no unusual amount of fluid present. A roentgenogram is invaluable in confirming the signs and evidences of a pathologic condition (even though the foreign body itself rarely makes a demonstrable shadow) and it will with certainty rule out empyema.

Next to diphtheria, the disease most likely to be confused with arachidic bronchitis is infective laryngo-tracheitis, especially the epidemic forms called influenza and the "grip." In these cases the symptoms will often clear up if the secretions are alkalinized by the administration of sodium bicarbonate. In other cases, only the bronchoscope will decide. A careful inquiry into the history of the onset, and a finding of whether or not an epidemic has been present and of whether or not the little patient has had access to peanuts should aid in the diagnosis. It may be mentioned that there are cases of influenza in children requiring bronchoscopy to prevent the little patients from drowning in their own secretion, in the same manner as in some of the cases of arachidic bronchitis.

We should always remember the possibility of peanut bronchitis when consulted regarding a child who

Fig. 1 (Case 2 [Fbly. 6471]). Portion of a temperature chart in a case of arachidic bronchitis; girl, aged 4; peanut in the right lower lobe bronchus for three days.

rather suddenly develops irregular fever, restlessness, dyspnea with cyanosis, paroxysmal cough, and the signs of a diffuse, generalized bronchitis, attended with wheezing respiration. A history of choking on a peanut, or of eating peanuts at about the time of inception of the illness, renders the diagnosis almost certain.

ETIOLOGY

Age.—One factor in etiology definitely established at the bronchoscopic clinic is that relating to age. No cases have been observed in adults. It may be assumed that this is partly because adults do not aspirate peanuts; if they did, symptoms would follow bronchial obstruction no matter what the substance, and it is reasonable to assume that at least a few such cases would have come to the bronchoscopic clinic. The

4. Jackson, Chevalier: A New Diagnostic Sign of Foreign Body in Trachea or Bronchi, the "Asthmatoid Wheeze," *Am. J. M. Sc.* 156: 625 (Nov.) 1918.

reaction in children is so diffuse as to indicate an etiologic factor independent of obstruction. Be the reason what it may, the fact remains that the only cases of arachidic bronchitis that have come to the bronchoscopic clinic have been in children. A closely related fact is that the severity of the symptoms has been in inverse ratio to the age. Other data and observations on etiologic will be considered under pathology.

PATHOLOGY

All of the peanuts aspirated had been roasted, so that it has not been possible to determine clinically whether the intensely irritating quality is lessened or increased by the action of heat on the raw tuber. Judging by analogy in similar organic materials, we may infer that the property of irritation is possessed by the raw peanut also, for violent diffuse tracheobronchitis was produced in several cases by the aspiration of walnut kernels and unroasted coffee beans. In one case, a pistachio kernel in the bronchus produced the identical symptoms of peanut bronchitis. A kernel of corn (maize) also acted in a similar manner, although the general reaction and evidences of toxemia were not so marked as in the peanut bronchitis. The peanut, however, seems to be peculiarly toxic when retained in the lower respiratory tract, and various explanatory hypotheses have been suggested by W. M. L. Coplin.⁵

(a) The action on the mucosa of irritating chemical substances present in the peanuts, either naturally, as in ricin in the castor bean, or developed in the process of roasting. The peanut contains 25 per cent. of protein, of which two globulins have been isolated—arachin and conarachin. Conarachin has the outstanding characteristic of containing more basic nitrogen than any other seed protein. Arachidic acid, a saturated fatty acid, is present in about 5 per cent. strength in peanut oil.⁶ A fruitful field for investigation is open in the testing of the individual substances in the bronchi of animals.

(b) Is the reaction the result of the presence of an alien protein parenterally introduced?

(c) Does the porous organic vegetable protein afford a protective matrix for the proliferation of bacteria, the bacterial growth liberating toxins or acquiring virulence to enable the organisms to attack the living tissues?

"Peanut thresher's fever" is well known to practitioners in the districts where the peanut is grown. Whether it is due to particular qualities inherent in the peanut plant and its tubers, or only to the great clouds of dust, acting simply as a multitude of foreign bodies, is a question on which we could get no information in medical literature. It has been observed by members of the dental profession that some teeth are more sensitive to peanuts than to sweets.

The endoscopic living pathology is evidenced as an edematous, generalized, purulent bronchitis, with accentuation of the morbid processes at the site of lodgment of the peanut kernel. In one of the cases, patches of exudate were seen, and in all of the cases there was a copious secretion of thick pus, which sometimes was so abundant as to drip from the bronchoscope. The degree of reaction to the foreign body

varies with the age of the patient; the younger the child, the more severe the reaction. In three cases in which we were not permitted to do a bronchoscopy, the patients died within two weeks. From the reports in these cases, as well as from observations in the nearly fatal cases that came in early enough for the patient to be saved, it seems evident that the younger children succumb after a short time from exhaustion incident to their constant fight for air and their hectic efforts toward the expulsion of the pus; or from toxemia produced by the absorption of the toxins of the retained purulent lung secretions; or, probably, from both combined. In older children, if the peanut is not removed, lung abscess develops in the portion of the lung distal to the foreign body. Removal of the foreign body, if the general condition of the patient is not too serious, is usually followed by a prompt subsidence of the dyspnea and cyanosis; the secretion loses its tenacious character, becomes more fluid and easier to expel and, in a few days, grows mucoid, greatly lessened in amount, and shortly ceases. The fever leaves in a little time, and the patient shows continued improvement in his general condition almost from the moment the peanut kernel is removed.

It is important to note that in all our various foreign body cases in which, prior to admission, the pleural cavity had been explored by puncture or by rib resection, no evidence of a pathologic condition was found. The impairment of resonance and the diminished transmission of breath and voice sounds are due, we have believed, to the accumulation of secretions in that part of the lung distal to the foreign body which is obstructing the bronchial drainage. To this condition, at the suggestion of Dr. George C. Johnston, we have applied the term "drowned lung," the pus being in the bronchi, to distinguish it from lung abscess, in which more or less of a pathologic cavity contains the pus (Fig. 2).

TREATMENT OF PEANUT BRONCHITIS

Having by history, physical examination and roentgenographic study made the diagnosis of peanut bronchitis, the physician should place the patient, as soon as possible, under the care of an endoscopist. The possibility of the kernel being coughed up is very doubtful, because, owing to its small size, it is usually drawn quite deeply into the bronchial tree, lodging in one of the smaller divisions, in which the expulsive force is limited; the edematous swelling of the bronchial mucosa tends further to fix the intruder. The longer the peanut kernel remains *in situ*, the greater the damage it produces, so that delay, with the hope and expectancy of the kernel being spontaneously expelled, should never be considered.

If the child is in good condition and but little dyspnea is present, immediate bronchoscopic removal of the peanut will in but a short time completely relieve all symptoms. The after-treatment of peanut bronchitis is largely nursing and providing the patient with an abundance of fresh air.

If, on the other hand, urgent dyspnea is present, and the child is obviously unable by hectic efforts to rid the air-passages of the thick secretions, tracheotomy should be performed. It is wise to do the tracheotomy early and not wait for the signs of exhaustion and intense toxemia, which may render the operation ineffective. Removal of the peanut at this stage would not relieve the dyspnea caused by the edematous laryngo-tracheobronchitis, although the pus accumulation

5. Jackson, Cleveland: *Surg. Gynec. & Obst.*, 28: 201 (March) 1919.

6. From chemical data kindly furnished by Prof. P. B. Hawk, Department of Chemistry, Jefferson Medical College of Philadelphia. Arachidic acid was suggested as a possible irritating factor by Jacob Rosenbloom.

could be thus removed. Furthermore, the insertion of the bronchoscope through the already damaged larynx would probably precipitate the tracheotomy. The tracheotomy will relieve the dyspnea and allow the removal of the secretions, and thus will lessen the toxemia.

After the tracheotomic wound has sufficiently granulated and the patient has recovered from the fatigue and exhaustion accompanying arachidic bronchitis, the peanut can be removed by bronchoscopy through the mouth. Passing the bronchoscope through the tracheotomic wound has decided disadvantages, and is never practiced in my clinic, even when, as in these arachidic cases, the tracheotomy has already been performed for dyspnea and drainage of the bronchi. It is important in the dyspneic cases not to use general anesthesia for either the tracheotomy or the bronchoscopy; for as soon as the patient loses consciousness, the action of the voluntary muscles of respiration ceases and the patient immediately stops breathing. Morphine is also contraindicated because it paralyzes both the respiration and the cough reflex.

ANALYSIS OF SOME RECENT CASES

An analysis of sixteen recent cases in which portions of peanut kernel had been removed from the bronchi is rather interesting. The oldest patient was aged 6, and the youngest 17 months, the average age being 3 years. The mortality was 17.6 per cent.—all the fatal cases being in the younger children, the oldest of these being 23 months and the youngest 17 months of age. There was no reason to believe that the mortality was due to the bronchoscopy, as these patients were admitted in extremely bad condition. The mortality in bronchoscopy for metallic substances is practically nil. Thirty-five per cent. of the cases of arachidic bronchitis required tracheotomy to relieve the urgent dyspnea, which is a constant symptom, varying in degree, but present in all of the cases, and to facilitate the ridding of the air-passages of the thick, tenacious secretion which the child is unable to expel through the impaired glottis. The tracheotomy was not performed for the purpose of inserting the bronchoscope, so-called lower bronchoscopy, for in all the cases the bronchoscope was inserted through the mouth, and the foreign body so removed. The longest time of sojourn of the peanut kernel in the bronchus was forty-eight days in a child, aged 2½ years, who recovered; the shortest stay was one day in a child of 17 months; and in this transient period the reaction was so great that the little one succumbed.

It is seen that all of the cases occurred in children, and that the younger the child the more severe was the reaction to the foreign body, and the more doubtful the outcome. Prompt tracheotomy, when urgent dyspnea is present, is a life-saving measure, for even

after the peanut is removed the edematous laryngo-tracheobronchitis does not immediately subside; and being unable to expel the thick, tenacious secretion through the glottis, the necessary cooperation of which, in the bechic cycle, is impaired by the subglottic edema, the child is drowned in its own secretions.

The longer the stay of the peanut in the air-passages, the greater is the reaction. The resistance of the older children is relatively stronger; but a prolonged stay will in any case result in lung abscess which, unrelieved, is fatal.

REPORT OF CASES

The following cases were selected from our records as typical of the varying degrees of reaction resulting from the aspiration of peanut kernels:

CASE 1 (Fbly. 347).—A boy, aged 1 year, 11 months, thirty days before admission, was eating peanut candy when one of his older playmates slapped him on the back and caused an intense choking and coughing attack. On the next day the patient developed a severe cough and had a temperature of 104 (rectal), which lasted two days and then returned to

normal. The temperature became elevated six times in a month and, after a few days, would return to normal. During the intervals of normal temperature the child coughed severely but would play with his toys, becoming very ill at other times. He lost rapidly in strength and weight. On admission it was noted that he looked ill and had dark, hollow circles under his eyes. His temperature was 104. A physical examination by Dr. John W. Boyce disclosed the respiratory movement of the right side to be almost abolished. The left side appeared fuller than the right. The percussion note was impaired, almost dull all over the right side, the impairment increasing toward the base. Breath sounds over the right upper chest were loud and harsh, but diminished in intensity over the lower lobe. A few small and medium moist rales were scattered over the

Fig. 2 (Case Fbly. 444).—Drowned lung resulting from the blocking of a branch of the left inferior lobe bronchus by a pistachio nut; note sharp limitation of the involved area.

right side. There was severe paroxysmal coughing, and the breathing was labored and accompanied by wheezing which could be heard across the room. Some cyanosis was present, and the patient's general condition was extremely poor.

The roentgenogram showed shadows over the right chest, although the impairment of resonance was greater than the density of the shadow would have indicated. The roentgenographic report (by Dr. George C. Johnston) was: "Decided evidence that right lower lobe bronchus is plugged. Left clear. Distinct shadow over right lower lobe, opaque enough for pus."

Without anesthesia, local or general, a bronchoscope was introduced, and a large amount of foul pus and slough was removed and an abscess cavity evacuated, after which a portion of peanut kernel was found lodged in the right lower lobe bronchus and removed. Only transient improvement followed. The air-passages were again quickly filled with pus, and urgent attacks of dyspnea and laryngeal spasms occurred. A tracheoscope was inserted through the mouth, and a number of sloughs which had lodged in the subglottic region were removed by means of it. The laryngeal spasms then subsided. One of the sloughs was ringlike and was considered a part of a bronchial wall. The dyspnea again recurred, however, owing to the copious outpouring of pus

and the inability of the child to expel it, so that a tracheotomy was performed which, aided by careful nursing, relieved the dyspnea. There was a slight improvement in the lung condition, and the patient was discharged to his home with the hope that an antituberculous regimen would restore the damaged lung; it was reported, however, that no improvement followed, and that the child died two months later.

The interesting points of this history are:

1. The prompt reaction to the foreign body, as evidenced by the temperature of 104 within twenty-four hours.

2. The intermittence of the symptoms; probably accounted for by wedging of the peanut kernel at times in the bronchus, and by the accumulation of secretions and the toxic absorption therefrom; succeeded, in turn, by the dislodgment of the foreign body for a time, possibly by the pressure upward of the accumulating secretions, a subsidence of temperature occurring after the drainage of the drowned lung.

3. The progressive failure of general health.

4. The excessive quantity of pus and the difficulty with which children expel it.

5. The relief afforded by tracheotomy in the lessening of the dyspnea and in the removal of secretions which the child could not expel through the larynx.

6. The extensive destruction of lung tissue by abscess formation, which rendered the removal of the exciting cause—the peanut kernel—unavailing.

7. The fatal outcome resulting from the prolonged retention of the peanut kernel in the bronchus.

CASE 2 (Fbdy. 647).—A girl, aged 4, brought to Jefferson Hospital, had choked while eating peanuts three days before admission, and had become very cyanotic for a period of about half an hour. Within twenty-four hours a severe cough and fever developed, and urgent dyspnea with cyanosis prompted the mother to consult a physician, who introduced bougies into the esophagus.

On admission there was urgent dyspnea and a purplish cyanosis; the child was extremely toxic and mildly delirious. Smears made from the larynx showed organisms resembling the diphtheria bacilli. A thick purulent secretion was seen in the larynx but no membrane. Diphtheria antitoxin was given, and tracheotomy was immediately performed, in order to relieve the dyspnea and allow the removal of the secretions. The dyspnea was relieved, but recurred frequently, owing to the accumulation of the tenacious pus, and necessitating frequent removal of the cannula and wiping of the secretion from the trachea.

A physical examination by Dr. E. E. Graham revealed a generalized bronchitis, with a small area of consolidation at the left apex posteriorly. A roentgenographic study by Dr. David R. Bowen disclosed a marked peribronchial thickening on both sides, but no pathologic shadows which would warrant his saying that in any one spot there was a foreign body. Later bacteriologic reports from cultures were negative for diphtheria bacilli. It was decided not to perform a bronchoscopy at this time because of the marked improvement following the tracheotomy, and because of the indistinctness of the physical signs and the roentgenographic examinations, which rendered doubtful the presence of the peanut. The tracheotomic cannula was removed after three weeks. On the day following the removal of the cannula, the patient again became dyspneic and cyanotic and seemed unable to expel through the larynx a thick, yellowish, tenacious sputum. The tracheotomic wound was reopened and the cannula reinserted; but with such slight improvement of the dyspneic signs that bronchoscopy was decided on. It was done through the mouth and after removing a large amount of the secretion by bronchoscope sponge pumping a portion of peanut kernel was found in the right lower lobe bronchus and removed. No anesthetic was used, and the operation required five minutes and twenty-six seconds. Con-

tinued improvement followed; the secretion became more fluid and finally ceased; the tracheotomic cannula was removed, and the patient was discharged well.

The resemblance to laryngeal diphtheria in the early symptoms in this case is noteworthy, and the life-saving effect of the tracheotomy is well illustrated, for the symptoms partly subsided under the increased drainage and relief from dyspnea afforded. The prompt recurrence of the symptoms on removal of the cannula is a further proof that much of the disturbance is due to retention of the viscid secretions and to absorption of toxins therefrom.

CASE 3 (Fbdy. 448x).—A girl, aged 6, was referred with the statement that twenty-four hours previously a peanut kernel had been aspirated. Much coughing and choking followed the accident, and within twelve hours the temperature was 102, respirations 42 and pulse 126. On admission the face was flushed and there was some dyspnea. The pediatrician, Dr. H. T. Price, reported a severe bronchitis on both sides, worse on the left. A roentgenographic study was not obtainable.

Bronchoscopy revealed all the air-passages filled with blood-stained pus: A portion of peanut kernel was removed from the orifice of the left upper lobe bronchus, and was followed by a gush of pent-up pus. The little patient was discharged well four days later.

The peculiar, irritative action of the peanut kernel is well exemplified by the prompt reaction noted in this case, as well as by its equally prompt subsidence on the removal of the peanut. It is also to be noted that the child was older and therefore more resistant to the pathogenic agent, whatever it may be, inherent in the peanut kernel.

Complete detailed reports of other cases will be published subsequently.

CONCLUSIONS

1. The aspiration of peanut kernels into the bronchi of children causes a definite syndrome which we term arachidic bronchitis.

2. There seems to be some inherent property in the peanut rendering it far more irritating than other forms of foreign body in the bronchi.

3. The instances which we have seen of this arachidic bronchitis have all been in children, and the younger the child the more severe was the reaction.

4. The pathologic condition consists of an edematous, purulent, laryngotracheobronchitis which, if not fatal, results in lung abscess.

5. The symptoms are due to (a) the swelling of the mucosa of the air-passages, resulting in dyspnea and cyanosis, and (b) the accumulation of the difficultly expelled purulent lung secretions, and the absorption of toxins therefrom, which results in fever and other signs of toxemia. The condition must be differentiated from laryngotracheal diphtheria and influenzal laryngotracheobronchitis.

6. The prognosis is grave if the peanut is not removed. The younger children succumb quickly to exhaustion and toxemia. If the peanut is promptly removed, convalescence is usually rapid. Resistance in the older children renders the course more protracted, but lung abscess ultimately results.

7. The treatment consists in early bronchoscopic removal of the peanut in the cases in which there is only slight dyspnea. In cases in which dyspnea is marked, tracheotomy may be required to pipe air to the lungs and to facilitate the removal of the viscid, puru-

lent secretions, a bronchoscopic removal of the peanut through the mouth to be effected as soon as the wound has sufficiently granulated.

8. The number of the cases and the definiteness of the symptoms, together with the serious nature of the reaction, warrant the inclusion of arachidic bronchitis among the diseases affecting the lower respiratory tract of children.

1830 South Rittenhouse Square.

ABSTRACT OF DISCUSSION

DR. EDWIN E. GRAHAM, Philadelphia: What I have to say will be purely from the standpoint of the pediatricist. Perhaps it would be well for me to give you the impression I had on seeing my first case. An infant was suffering from inspiratory dyspnea, a typical case. The child was more or less cyanosed. Inspiratory dyspnea to the pediatricist means what it would to the laryngologist, obstruction of the larynx, and I thought of laryngeal diphtheria. I asked the intern whether he had made a smear. He had. A culture? Yes. Had he given antitoxin? Yes. But Dr. Jackson had told him that this child had inhaled a peanut. On closer examination I found well marked bronchitis in both lungs, which we do not get in laryngeal diphtheria; I found this child was toxic and running an irregular temperature, which we do not have in laryngeal diphtheria. In laryngeal diphtheria the toxemia and temperature come late. The child had only been sick twelve hours, which certainly suggested laryngeal diphtheria. In peanut bronchitis the voice is husky, rarely lost as in membranous croup. The lung symptoms were more or less localized in one portion of one lung and although it is not always possible by auscultation and percussion to locate the peanut, still you can make a guess as to where the peanut is in a fair proportion of cases. The peanut commonly does not make a shadow with the roentgen ray. One of the symptoms which impressed me most was the constant and persistent cough, evidently due to the large accumulation of thickened mucus to which Dr. Jackson refers and which is distributed throughout both lungs. When one understands the pathology, and the fact that this child is suffering from laryngitis, tracheitis and bronchitis, of course the symptomatology is clear, but as far as I know the books on pediatrics do not discuss peanut bronchitis, and when Dr. Jackson tells us that this is the third paper that has been read on the subject, perhaps we are to be excused. Certainly, the literature on the subject has been so scant that neither the laryngologists nor pediatricists have known much about it. The younger the child the more severe are the symptoms and in the infant under two years of age the symptoms developed in a few hours. A history of choking with severe dyspnea and possibly eating peanuts helps in the diagnosis. Tracheotomy in the infant is often necessary and does much good.

DR. THOMAS HUBBARD, Toledo, Ohio: I have encountered cases of peanut bronchitis and also of pneumonia and have attributed the causation to a saprophytic infection—peanuts are very often moldy—and also as to the other infections. The peanut has usually been subjected to more or less mastication and coincident mouth infection may be carried into the bronchi. Another factor which I have thought was important in causing the violent bronchitis which often follows aspiration of a peanut is the fact that the child who aspirates the peanut has been eating peanuts. There are many small fragments of peanuts in the mouth and undoubtedly at the time the peanut is aspirated the small fragments find their way into the smaller bronchi. Probably the attack of coughing is primarily due to a small piece or pieces being inhaled and the larger mass is then aspirated. This was impressed on me at a necropsy made years ago on a patient who died a few hours after the onset of a double pneumonia. We found small fragments of peanut scattered through the smaller bronchi on both sides. It is these little fragments which probably account for the pneumonia in this type of case. As to peanut bronchitis in adults: A patient came to me on account of bronchitis of about a month's duration.

Nothing was said about a foreign body. I examined her and located a one sided bronchitis; then, in a routine way, I asked her if there was any possibility of foreign body aspiration. She remembered that about four weeks before she had choked on a peanut, but she said she had coughed up the skin of the peanut and thought that was the end of it. It is interesting also to mention that she arranged to go to the hospital the next day, but that night she coughed up the peanut.

DR. JOHN W. MURPHY, Cincinnati: I have had several cases of peanut bronchitis in children, and in each the history has been that the child was eating peanut candy, and I suppose that would account for the child having peanut fragments in the bronchi. I have always been impressed with the small size of the foreign body. It seems almost impossible that a very small portion of peanut could produce the intense bronchial symptoms manifested in these cases. A child, six years of age, aspirated a peanut and it was removed with much difficulty three or four days later. The following day the child seemed to be doing nicely. I went into the next room, and in fifteen minutes the nurse came running in and said, "the child is dying." I found the child in a state of complete collapse. What had happened? There had been an excessive secretion of rather thick mucus which had suddenly come up into the trachea and the child had suffocated, almost the same as if a large body had been inspired suddenly. A rapid tracheotomy was done. The trachea was completely occluded by the foreign body. Even though we passed the bronchoscope several times and succeeded in removing a substance considerably larger than the ordinary foreign body found in such cases, it proved each time to be inspissated mucus.

DR. H. P. MOSHER, Boston: Dr. Jackson said tracheotomy is dangerous in these cases. I would like to ask him why. Also why he condemns the use of morphin in those cases where we think it necessary.

DR. FENTON B. TURCK, New York: Dr. Jackson has taught us that bronchially lodged foreign proteins do not produce reaction. Therefore, meat and bone do not produce this reaction of pneumonitis even though infected, but if a foreign body reaches the bronchi and causes destruction of the tissue by cell digestion, it produces this reaction of pneumonitis. If meat is cooked it has no particular effect in the bronchi but substances which cause rapid tissue destruction or substances containing ferments which digest the tissue produce this reaction of pneumonitis. We are dealing not alone with a foreign agent but with autolyzed tissue products producing their own reaction in the body. Dr. Jackson has shown by his clinical observation and experimental work that tissue autolysis produces what we now call bronchopneumonia, bronchitis and similar conditions under a variety of names.

SIR ST. CLAIR THOMSON, London, England: Of course, we all recognize that in these matters we may say of Dr. Jackson as Michael Angelo said of Titian, that he eclipsed all his predecessors and sterilized all his successors. I came here, like Dr. Mosher, without a dictionary, and I have just written here to Dr. Dean, "I am ashamed to say that I do not know what 'arachidic' means." It was therefore a great relief when Dr. Graham came to my rescue by calling it "peanut bronchitis," because I really only understand English. There I feel at home. We do not have peanuts in England; we call them "monkey nuts." Also, our children are not so advanced as are your children. We do not feed them monkey nuts. Dr. Graham said he saw an infant with inspiratory dyspnea. Of course, I do not know what the limit of infancy is in this country. I should judge it would be about three weeks. In England we short petticoat a child at the end of four months, but here I suppose it is a full grown adult at that time. We also feed them with milk or some simple diet; here it seems to be peanuts and chewing gum. Evidently, also, they do not require teeth, as Dr. Hubbard said that in his case the peanut was not sufficiently masticated. Of course, it was from America that we learned about dethatching our food, but evidently infants are not taught it. Now, coming to what interests us, I hope I gather correctly from Dr. Jackson that if the patient does not have sufficiently localized symptoms, and yet the symp-

ions are serious, he does a tracheotomy. I would like to know whether after the tracheotomy he follows the ideas of one of our British statesmen, does he wait and see? Because I think in many of these cases, if there is no urgency and a tracheotomy is done, we should wait and see. We ought to give Nature a chance, although I do not think that in America Providence has much to do with it, you are generally ahead of Providence; still there is such a thing as self determination even in the human body, and after Dr. Jackson has done his tracheotomy, in order to live up to his ideals, does he wait until the tracheal wound closes before he goes in through the mouth? I did not quite follow him. If he goes in through the mouth with a tracheotomy wound in the neck, it seems to me like a burglar, who, going into your basement and seeing in the cellar some things he wants, goes around to the front door and down to the cellar when he might easily have gone down from the basement. But whatever Dr. Jackson insists is the fact, whether he defends his own position, as no doubt he will do, I still feel that there are many like myself who must agree that a good deal of Dr. Jackson's advice is, as the poet says, "Too wise and good for human nature's daily food."

DR. CHEVALIER JACKSON, Philadelphia: The paper spoke very learnedly about physical signs, but for brevity's sake I omitted the names of the different men who are responsible for those physical signs, as you probably know that I could not tell you on which side a pneumonia was, by my own individual auscultation and percussion. It is only by association with Drs. McCrae, Graham, Boyce, Price and others who have worked with me that I am able to give a résumé of what the physical signs have been in the cases of arachidic bronchitis. Dr. Hubbard's point is worthy of consideration. He spoke of peanuts being of septic character from being chewed in the mouth. That is equally true of fragments of teeth and other dental objects, and especially of bones, which are of all foreign bodies in the bronchi the most putrid, yet they do not produce more than a localized reaction. A patient's temperature will not rise and there will be no particular illness from aspirating a piece of bone if it does not obstruct drainage. Therefore it cannot be true that it is infection carried from the mouth produces the peanut reaction. In regard to there being a multiplicity of fragments, we have reason to doubt that this is the causative factor in the reaction that is produced by the peanut. We have had many cases in the hospital going along day after day with a temperature of 103 or 104 F. While we are deciding whether or not to use the bronchoscope, but finally, introducing the bronchoscope, we have taken out a piece or two of peanut, and immediately the temperature has fallen and the patient promptly recovered. If it were unremovable multiple fragments in minute bronchi instead of one fragment in a larger bronchus, the patient would not have gotten well. Dr. Murphy made a good point in saying that peanut candy is a common cause of this condition. Children without molars are given peanut candy; of course they cannot chew, but they are given the candy and in a great many instances this has been the source of the peanut kernel in the bronchi. His impression as to the small size of the fragments corresponds to my own. I have been impressed in a number of cases with the relatively small size of the peanut kernel; but the subsequent recovery proves that the relatively small piece of kernel was the cause of the illness. Dr. Mosher's remarks are important contributions to the subject. Tracheotomy was mentioned in connection with cases where we had to save the child from asphyxia. It was not for the purpose of inserting the bronchoscope, but to give the child air and to get out thick secretions and tide the child over until he got in condition for a bronchoscopy. The bronchoscopy was always done through the mouth, not for the sake of the technique, but simply that it is easier to work with the bronchoscope through the mouth in the old way than when it is put through the neck with the head in the way. The tracheotomy route has no advantages. If the bronchoscope is inserted, the patient's head being conceded, no observer can tell by looking through the tube whether it went in through the tracheal wound or through the mouth. Tracheotomy for the insertion of a bronchoscopic is a relic

of the developmental stage of bronchoscopy. In regard to using morphin, until I went to Philadelphia I was afraid to use either morphin or cocain in children, and I never used them. But when I arrived in Philadelphia Dr. Graham and Dr. Hare said morphin at least could be given with perfect safety if given with proper precaution. Under their careful guidance I used it in older children with complicated mechanical problems of disentangling foreign bodies and have found it of the utmost value, although I think it must be used with care and discretion in selected cases and in older children only. I am glad of the corroboration in Dr. Turck's remarks, but I must disclaim credit for the hypothesis of the alien protein; that was the suggestion of Dr. Coplin of Jefferson Hospital. Sir St. Clair Thomson is altogether too modest in saying that he understands only English. I heard him give an address at the Congress in London in three different languages successively and heard him translate into three or four different languages the words of different speakers. So I must say he is the master of many languages instead of one, and he is also a master of the bronchoscope.

GANGRENE FOLLOWING CARBON MONOXID POISONING

J. EMMONS BRIGGS, M.D.

BOSTON

REPORT OF CASE

Sunday morning, December 22, the three O'Connell brothers left Warren Bridge in their motor boat, for a fishing trip in Boston Harbor. The day was beautiful and warm. All the brothers went forward. After passing the narrow gage ferry, Cornelius went into the cabin to lie down.

The cabin was 15 by 7 feet. Before starting on the trip, Cornelius had disconnected the exhaust pipe preparatory to installing another muffler. This exhaust was ordinarily carried out along the bottom of the boat, but the pipe was disconnected within 3 feet of the engine, leaving the open exhaust in the cabin.

Fig. 1.—Condition of hands before operation.

When they approached Apple Island, Timothy asked John to go into the cabin and arouse Cornelius. After fifteen minutes, John had not returned and Timothy noticed through the open door that he had fallen suddenly forward. Timothy shut off the engine, rushed in and found Cornelius lying on the floor about 8 feet from the engine. John was within 4 feet of the engine and was dead.

Cornelius at this time was still breathing. He was carried out of the cabin and efforts were made to revive him. At first, he talked incoherently. The police boat was signaled and they were towed in. When they arrived at the wharf,

John was pronounced dead and Cornelius was taken to an emergency hospital and the following day was transferred to another hospital, where he remained a week.

He was treated for what appeared to be second degree burns of both hands and feet. His record in that institution states that the backs of both hands and feet were covered with large tense blebs. These were punctured and trimmed off, and boric ointment dressings were applied. After leaving the hospital, he was attended by his physician, who continued

Fig. 2.—Superficial gangrene of feet.

treatment, but soon observed that the affected areas were increasing in size and extensive gangrene was developing.

He was admitted into my clinic, Jan. 24, 1919. On admission, his condition was as follows:

Right hand: Gangrene involved the entire three middle fingers, one half of the inner border of the thumb and an extensive area of the little finger. The left hand showed gangrene of the distal phalanges of the four fingers and flexor surfaces of the thumb. Gangrenous areas were on the outer border of the tibial region, the external malleolus, the outer border of the dorsum of the foot, and small patches on three toes. On the left foot, there were gangrenous areas at distal end of two toes.

It was evident from the location and character of the lesions that they could not have been produced from contact with heat. The type of gangrene differed widely from any previously observed by me. At the time the patient entered our hospital, the blebs which resembled burns had entirely passed away. Situated beneath these areas, a dry gangrene was present. This necrosis attacked the skin, muscle tissue, tendon, periosteum and bone, and entered several joints.

Lines of demarcation were well established. On the left hand, the tips of the fingers were entirely necrotic. On the right hand, the ends of the fore and middle fingers were viable, while extensive gangrenous areas involved the dorsum of both these fingers. It is impossible to conceive of a burn producing areas thus distributed.

Examination of the blood and urine were negative. Absence of sugar, which is frequently present in carbon monoxid poisoning, is accounted for by the long interval which had elapsed since the intoxication.

January 28, thirty-seven days after the accident, amputations were performed as follows: On the right hand, the three middle fingers were disarticulated at the metacarpophalangeal joints. On the left hand, four fingers were amputated midway in the second phalanx. As amputations were made in septic areas and as attempts were made to save all tissue possible, the flaps were only partially drawn together and ample drainage was provided.

As will be seen by referring to Figure 1, an area of necrosis remained on the dorsum of the middle finger and the thumb of the right hand. This destructive process continued, entered the second phalangeal joint, and resulted in deformity and ankylosis. Perhaps amputation of the little finger would have been desirable, but this can be done at a later time.

Figure 2 illustrates a more superficial type of necrosis, from which the patient ultimately recovered without the loss of any toes. The necrotic areas on the dorsum and outer aspect of the right foot, after sloughing deeply, finally healed by granulation.

PREVIOUS CASES

In connection with the foregoing, the two similar cases recorded in the literature may be of interest, and brief abstracts are appended. They are reported, respectively, by Alberti¹ and by MacLean.²

Alberti reports extensive gangrene of the musculature of the throat and paralysis of the left leg in consequence of carbon monoxid intoxication. This patient, W. Kaupé, was overcome with carbon monoxid escaping from a stove. When he awoke, he saw that the woman lying beside him was dead. Her face was congested and swollen and covered with tabloid vesications. He had stabbing pains in the head, and on attempting to rise, he fell unconscious. A paralysis of the right foot and painful swelling of the right elbow appeared, with pain in the arm and stiffness in the neck. On the right side of the neck, there was a brownish black mummified area, the size of the palm of the hand, which remained entirely dry and was surrounded by a line of demarcation. It was necessary to incise to the depth of 2 cm. before blood, mixed with dark brown fluid, appeared. The gangrenous area on the neck and right elbow extended, and he died twenty-six days after the intoxication.

The case of MacLean showed carbon monoxid poisoning resulting in gangrene of both legs. The patient was found unconscious in his room with a small gas burner open, in which the flame had been accidentally extinguished. The gas contained 7 per cent. carbon monoxid. A week later, the patient complained of pain in the feet and legs and was readmit-

Fig. 3. Hands after amputation.

ted to the hospital because both feet and legs were swollen and discolored in patches, the discoloration extending below the knees. During the next two weeks, the pain continued, the legs became edematous, and discoloration increased to gangrene. The right leg was amputated, January 9, and the left, January 13. Recovery followed.

THE SURGICAL TREATMENT OF
TYPHOID CARRIERS*H. J. NICHOLS, M.D.
Lieutenant-Colonel, M. C., U. S. ArmyJ. S. SIMMONS, M.D.
Major, M. C., U. S. Army

AND

C. O. STIMMEL
Captain, Sanitary Corps, U. S. Army
WASHINGTON, D. C.

In this article we record the results of surgical treatment of six chronic typhoid carriers; one (a "urinary" carrier) was cured by nephrectomy, three ("intestinal" carriers) were cured by cholecystectomy, and two ("intestinal" carriers) failed of cure by cholecystectomy. The diagnoses and conclusions in the "intestinal" carriers have been based entirely on the outcome of cultures of the duodenal contents rather than on the outcome of cultures of the lower intestinal contents. Negative duodenal cultures are also recorded in a seventh carrier who had a cholecystectomy in 1913.¹ These results, while not perfect, are believed to be better than can be shown for any other kind of treatment available at present and are certainly better than the results of no treatment at all.

The literature of the treatment of typhoid carriers contains the record of a number of apparent cures following cholecystectomy² and the use of the roentgen ray,³ vaccines,⁴ lactic acid bacilli,⁵ and various drugs.³ These conclusions, however, are based almost altogether on the results of cultures of the feces. In view of our present knowledge of the pathology of typhoid carriers and of the differences between cultures of the bile and those of the feces, these apparent cures are open to some question. On the other hand, a number of failures have been reported even with only feces cultures as a standard of cure. These cases are, of course, of definite negative value. Failures following cholecystectomy⁶ will be referred to later. In general, it may be said that the future literature will be much more valuable than the past literature if workers will confine their reports to cases which have been examined by aid of the ureteral catheter and duodenal tube.

CONTROL OF COMMUNICABLE DISEASES

Shortly after the declaration of war, the Surgeon-General's Office prepared directions for sanitation and for the control of communicable diseases in the Army which were issued by the War Department as Special Regulations No. 28.⁶ Paragraph 28, *b* and *c*, is as follows:

(*b*) No man should be employed as cook or handler of food or water who is a carrier of *B. typhosus*, *B. paratyphosus* A or B, or cysts of *Endameba histolytica*.

(*c*) Stools of all cooks and food handlers (including handlers of water and drivers of water and ice wagons) will be examined for typhoid, paratyphoid A and B, and dysentery bacilli, and for cysts of *Endameba histolytica*. In case of enlisted men, notation of positive findings should be made on the service record.

As a result of these regulations, a large number of men were examined and a small number of typhoid carriers were found. Exact percentages of the carrier rate cannot be given, as not all carriers were reported and all the examinations were not satisfactory; but the number of men examined in the first six months was about 30,000. Routine examinations were also made

of convalescent typhoid patients, and two carriers in this series were found in this way who were carrying typhoid bacilli five and six months after recovery from their fever. No paratyphoid carriers have come under observation to date. The disposition of these men was naturally more of a problem than the diagnosis. They were automatically relieved from duty as food handlers, and some were at first discharged from the service locally. On ac-

Fig. 1 (Case D). Left kidney; typhoid pyonephrosis; typhoid fever, 1912; left nephrectomy, May 28, 1918; cure.

count of the unusual opportunity afforded to study the carrier problem, it was decided by Col. F. F. Russell, in charge of the division of infectious diseases of the Surgeon-General's Office, to collect as far as possible all carriers at the Walter Reed General Hospital, Washington, D. C., for observation and treatment. Surgical treatment was considered the most promising in view of the pathology of the carrier state as seen experimentally in rabbits and on account of an earlier successful cholecystectomy, as well as of the results of various kinds of treatment recorded in the literature on this subject. Some of these men consented willingly to operation when the condition was explained. Others at first refused; but when it was made clear to them that during the war they were subject to court martial if they refused an operation that might fit them for duty, they also agreed to operation.

REPORT OF CASES

CASE 1 (record furnished by Major A. Kemble, Washington, D. C., in charge of case): *History*.—C. W. R., cook, 14th Ball-balloon Company, aged 21, white, in service four months,

⁶ Special Regulations No. 28, W. D., 1917, 22.

* From the Laboratory Service, Walter Reed General Hospital.

stationed at Omaha. The patient's father died of cancer. The family history was otherwise negative. The patient had had the usual diseases of childhood and typhoid fever in 1912-1913, lasting from October until January. Since May, 1916, he had had eight typhoid inoculations, the last three being in January, 1918. He said he had never had any symptoms referable to the genito-urinary tract. Venereal history was negative.

In the course of routine stool and urine examination of food handlers he was found to be a "urinary typhoid" carrier by Major Davis at Central Department Laboratory, Col. C. F. Craig in charge, March 20, 1918. April 13, he was admitted to Walter Reed General Hospital for observation and treatment.

He was a well proportioned man weighing 175 pounds and in generally good physical condition. The temperature was normal. There were no unusual symptoms or physical signs present. A specimen of bile obtained through a duodenal tube was negative for typhoid bacilli. The left kidney was palpable but only slightly enlarged. The urine was turbid in appearance and acid. The specific gravity was 1.014, and contained a heavy trace of albumin and numerous pus cells. Cultures showed a pure, rich culture of typhoid bacilli. The patient was transferred to the genito-urinary service, May 3, cystoscopy revealed a much congested bladder. Both ureteral orifices were normal and the bladder was otherwise negative. The prostatic orifice was normal and no residual urine was present. The ureters were easily catheterized. The flow from the left was very free and continuous, and two large test tubes of cloudy fluid were obtained. A normal flow and a normal fluid were obtained from the right. On these specimens the laboratory reported the following:

From left kidney: Cloudy with leukocytes, epithelial cells and threads of bacilli. Urea concentration: 0.005 in 1 c.c. The specimen contained a rich pure culture of *B. typhosus*. From right kidney: clear; calcium oxalate crystals. Urea concentration: 0.031 in 1 c.c. Culture: A few colonies of *B. typhosus* (probably from bladder). A thorium pyelogram revealed a large hydronephrosis of the left kidney. May 15, the function (phenolsulphonephthalein) on each kidney was: left, less than 1 per cent.; right, 22.5 per cent.

Operation and Result.—May 28, a left nephrectomy was performed by Capt. D. Borden and Captain Kemble. The pathologic report on the kidney and on the gallbladders in this series has been made by Capt. M. W. Lyon, Jr.:

"C. W. 15 s W. R. G. H. Kidney, 0.130 by 70 mm., weight 212 gm. It shows marked grade of hydronephrosis. The pelvis and calices are enormously dilated, the kidney being reduced to a shell varying from 2 to 5 mm. in thickness. Microscopic examination of one of the thin parts of the kidney shell shows an absence of kidney structure, the outer portion being a wall of new fibrous tissue and the inner a mass of infiltrating small round mononuclear cells" (Fig. 1).

The contents of the pelvis consisted of a thin turbid fluid containing leukocytes and a pure culture of typhoid bacilli. The wound was drained and the patient made an uninterrupted recovery. Cultures of the urine after operation for *B. typhosus* were as follows: May 20, +; June 1, +; June 3, —; June 10, —; June 30, —. Since June 30, the urine has been constantly negative. A small fistula was present for

five weeks after operation. A culture from this was negative for typhoid bacilli. July 6, cystoscopy revealed a bladder mucous membrane somewhat grayish in appearance and a mild degree of trabeculation; otherwise normal. August 29, the bladder was normal.

The patient went to limited service duty in good condition. This is a remarkable case of a typhoid carrier of six years' standing whose left kidney had become practically functionless but who had never had any symptoms. He was a cook and his urine was as rich in typhoid bacilli as a broth culture. Fortunately such cases are comparatively rare, but a somewhat similar case was recently reported by Ruediger.⁷

CASE 2.—A. V. McD., private, Unassn. Tr. Det., Camp Lee, Va., aged 27 (home, Lynchburg, Va.), was admitted in June, 1918, with typhoid fever. Typhoid vaccinations were given: one dose, June 3, 1918, and (patient's statement) three doses in 1917 before entering the army. Diagnosis of "typhoid carrier" was made by the laboratory at Walter Reed General Hospital from cultures of duodenal contents, Aug. 27, 1918. The urine was negative.

Nov. 19, 1918, the gallbladder was removed by Major J. A. Hill. "McD., A. V. 98 s W. R. G. H.; gallbladder; rather small and contracted, measures about 60 by 20 mm. The vessels are rather conspicuously dilated. The mucosa is dull reddish brown in color and under the surface the vessels are rather prominent. No stones are present." Contents of bladder showed a pure culture of typhoid bacilli.

Recovery was prompt and the patient is now in good physical condition. He was discharged as cured after two successive negative cultures of duodenal contents, March 4, 1919.

CASE 3.—W. O. L., private, 11th Cavalry, Fort Myer, Va., aged 22, was admitted, July, 1918, with typhoid fever. Typhoid vaccination was given, June, 1917. The patient was diagnosed as an intestinal carrier by Captain Spruit at the Embarkation Laboratory, Newport News, during convalescence. He was sent to duty by mistake, but was traced and sent to Walter Reed General Hospital, Jan. 31, 1919. Diagnosis of carrier was confirmed by duodenal culture.

Cholecystectomy was performed, Feb. 26, 1919, by Major E. M. Jones. "L., W. O. 164 s W. R. G. H., gallbladder, 70 by 30 mm. Its walls appear slightly thickened, but in general the organ appears essentially normal. The mucosa shows a few hyperemic spots and varies in color from a dull pinkish gray to much

larger areas stained greenish brown by bile. A sub-spherical stone almost black in color is present, about 8 mm. in diameter. It is roughened, resembling a mulberry."

1911. Triple typhoid vaccinations were given in February, 1918. Diagnosis of typhoid carrier was made from cultures of feces at Camp Green, N. C., Aug. 29, 1918. The patient was admitted to Walter Reed General Hospital, Oct. 18, 1918. The diagnosis was confirmed by cultures of duodenal contents. Nov. 12, 1918, the gallbladder was removed by Major J. A. Hill.

"W., M. 95 s W. R. G. H., gallbladder, 60 by 30 mm. The walls are of normal thickness. The large blood vessels in it are conspicuously dilated. The mucosa is hyperemic and light in color but otherwise appears normal. It contains a large, ellipsoidal, blackish brown stone, about 12 by 7 by 7 mm. In the wall of the bladder is an ill defined impression apparently caused by pressure of the stone" (Fig. 2).

The contents were golden brown and were positive for typhoid bacilli. Recovery was prompt and patient is now in good physical condition, and is on duty again without restrictions.

CASE 5.—J. L., cook, 106th Field Artillery, Camp Wadsworth, S. C., aged 39 (home, Niagara Falls, N. Y.), had had typhoid fever in 1911. Nine typhoid vaccinations were given in the three previous years. Diagnosis of typhoid carrier was made at the Army Medical School from cultures of feces made in routine examination of food handlers, Dec. 25, 1917. The patient was admitted to Walter Reed General Hospital, Jan. 9, 1918. Diagnosis was confirmed by examination of

duodenal contents, Jan. 15, 1918. Medical treatment with sodium bicarbonate and other drugs was unsuccessful. July 29, the patient's gallbladder was removed by Major F. J. Cotton.

"L., J. 42 s W. R. G. H., gallbladder. The gallbladder is much torn. The open organ measures about 50 by 35 mm.

It shows marked engorgement of vessels and the mucosa is pinkish to dark reddish in color. The organ appears small and the fundus contains five well marked stones of very irregular shape and ranging in size from about 10 to about 5 or 6 mm. in the largest diameter. About ten or twelve much smaller stones are present, also of irregular shape. The stones appear to be fragments of a larger stone and vary in color from a dull grayish to a pinkish and dark brownish. The stones appear to be confined to the fundic portion and have left well marked erosions on the mucosa. Around the neck of the bladder the mucosa appears more normal though it is congested." A pure culture of typhoid bacilli was recovered from the contents of the bladder.

This case was a surgical success but a bacteriologic failure, as thirteen successive duodenal contents cultures in eight months were positive. The patient was finally discharged with consent of the board of health of the state to which he went.

CASE 6.—E. P., private, 327th Infantry, Camp Gordon, Ga., aged 26 (home, Newberryport, Mass.), had had typhoid fever in 1900. Typhoid vaccination course was completed, Oct. 21, 1917. Diagnosis of typhoid carrier made by department laboratory, Southeastern Department, from cultures of feces made in routine examinations of food handlers, Jan. 3, 1918. The patient was admitted to Walter Reed General Hospital, March 28, 1918. Diagnosis was confirmed by examination

of duodenal contents, April 22, 1918. Medical treatment with hexamethylenamin and vaccines had been unsuccessful and, April 26, 1918, the gallbladder was removed.

"E. P., 1 s W. R. G. H., gallbladder. It appears rather small, measuring about 50 by 30 mm. It appears slightly thickened, the mucosa is rather bright reddish and the outside of the bladder shows considerable congestion. It contains a single spheroidal stone, about 10 by 7 mm. varying in color from light to dark brownish. On removal of the stone a distinct impression is left in the mucosa and sub-mucosa."

The contents which were colorless contained a pure culture of typhoid bacilli. The bladder ruptured during removal and the operative area was infected and convalescence was somewhat slow, but the patient entirely recovered and is now in good physical condition. However, his duodenal contents are still positive for typhoid bacilli, indicating that there is a focus probably in the bile passages of the liver. He has finally been discharged from the service with the consent of the board of health of the state to which he went.

CASE 7.—(1) M. M., private, first class, 2d Batt. Engrs., aged 38, had had typhoid fever, probably in September, 1910, in the Philippine Islands, "gastro-enteritis with fever." Diagnosis as typhoid carrier was made at Letterman General Hospital, San Francisco, from cultures of feces, Nov. 20, 1910. He was admitted to the Walter Reed General Hospital, April 10, 1911.

Diagnosis of typhoid carrier was confirmed at this hospital in April, 1911. The patient was given medical treatments with calomel, buttermilk, sodium sulphite, hexamethylenamin

and salol, ipecac and vaccines (stock and autogenous) for four months; all of which proved to be unsuccessful. Jan. 21, 1913, cholecystectomy was performed by Lieutenant Leary and the gallbladder was found to be enlarged and to contain a stone. Culture of the contents showed a pure culture of typhoid bacilli. Recovery was prompt and the patient was discharged, May 19, 1913, as cured.

The patient was examined in January, 1916, by Nichols in El Paso, Texas. His physical condition was good and

all cultures, including those of the duodenal contents, were negative.

The patient was reexamined, May 7, 1919, at this hospital. His physical condition was good and cultures of feces, urine and duodenal contents were negative.

COMMENT

The picture presented by sections of the gallbladder walls can be considered in one place, as it varied only

before a final report is made. Under these conditions we believe that a culture of duodenal contents is synonymous with culture of the bile. The point has been made that typhoid bacilli might reach the duodenum from the pancreas or from an infected diverticulum of the duodenum itself. There is no record in the literature of any lesion of the pancreas, and experimentally it has been found impossible to make typhoid bacilli pass through a gland which resembles the pancreas, namely, the salivary gland. On the other hand, there is ample experimental evidence⁹ that typhoid bacilli pass readily from the blood into the bile and in some cases establish themselves in the bile passages, especially in the gallbladder. We believe that culture of the good specimen obtained through the duodenal tube is equivalent to a culture of the bile and that this culture is the best evidence we can get on what is going on in the bile passages. Such cultures are of course much superior, from this point of view, to cultures of the feces,⁸ as may be seen from the failures reported above. Case 6 had eight successive negative feces cultures in one month, followed by a positive duodenal culture; and in several cases a negative feces culture and a positive bile culture occurred in the same day. We are of the opinion that in bile passage carriers the

TABLE 7.—SUMMARY OF CASES

in degree. The essential lesion is an infiltration of the submucosa with leukocytes of the mononuclear type and a few eosinophils. The epithelium is intact and no abscesses are seen in the muscular or fibrous coats. In the carriers of short duration the cells are confined to the submucosa; in the older cases a few cells are seen in the muscularis and fibrous coat, while the submucosa shows a chronic thickening.

In other words, the histologic evidence supports the conception that the cholecystitis occurs through infection of the bile, rather than of the blood.⁸ The same picture has been seen in an instance of cholecystitis occurring during typhoid fever, which probably represents the start of the carrier condition.

The standard of cure in these cases has been three successive negative cultures of duodenal contents, and is believed to be reliable provided good specimens are obtained from the patient and provided they are properly handled in the laboratory. The specimen should be neutral or slightly alkaline in reaction to litmus paper, and should show a golden yellow color and syrupy consistency characteristic of bile. The specimen should be cultivated directly, and also should be incubated for twenty-four hours and recultivated

bacilli are regularly excreted in the bile and that the term "intermittent" carrier should be dropped.

The principle underlying the surgical treatment of typhoid carriers is the excision of the focus of infection. The same principle applies to the now well established surgical treatment of diphtheria, streptococcus and meningococcus carriers by tonsillectomy. The foci of infection in chronic typhoid carriers are in the two chief excreting organs, the kidneys and the liver; or more specifically in their ducts: (1) the hilum of the kidney; (2) the biliary passages, especially the gallbladder. Pure "intestinal" carriers are not believed to occur any more than pure "urinary" carriers.

1. From an infected hilum, typhoid bacilli are fed into the urinary tract and appear in the urine. They may produce a secondary urethritis and cystitis; if only one kidney is involved and this is removed, the secondary inflammation disappears and the patient is cured.

2. From the bile passages, typhoid bacilli are fed into the intestine and appear in the intestinal contents only so long as the focus is present. There are three possibilities in regard to infection of the bile passages, (a) The gallbladder alone may be infected. In this case cholecystectomy results in cure. (b) The gall-

8. Nichols, H. J.: Gall Bladder Infections, *J. Exp. Med.* 24: 497 (Nov.) 1916

9. Nichols, H. J.: Alkaline Treatment of Early Gallbladder Carrier, *J. A. M. A.* 68: 958 (March 31) 1917

bladder and bile ducts in the liver may both be infected. In this case cholecystectomy does not cure the carrier condition. Cultures of duodenal contents are still positive. We have no way of determining in which of these two classes a given case falls except actual trial, but it is known that gallbladder carriers are more common than bile duct carriers. There is a third possibility (*c*), namely, the gallbladder might be normal and the bile passages alone might be infected. In this case also cholecystectomy would not be curative; but, from the evidence at hand, such cases must be very rare, if indeed they occur at all.

We are not competent to discuss the strictly surgical aspects of these cases, but are, of course, interested in the outcome from an operative as well as from a bacteriologic point of view. In operations such as these, which are done more for the good of the group than of the individual, it is necessary to insist on excellent surgical technic and judgment, in order to avoid a fateful tragedy such as that which befell a medical officer who had been taking care of meningitis cases and who expected to go home on leave to visit his wife and baby. Although his throat cultures were negative for meningococci, in order to be doubly sure that he was not a carrier he had his tonsils removed and died of hemorrhage.

In the cases mentioned, the operative results were good, although in one case there was what is called a stormy convalescence. The gallbladder was removed from below in some cases and from above in others. The cystic duct was found normal in all. It is obvious that these cases should be worked out with full cooperation between the pathologist and the surgeon. Whether a new specialty of "carrier surgery" should be established to handle this growing field need not be discussed here, but there should be a full understanding about the situation. The laboratory man has taken the initiative in this field and has asked for assistance from the surgeon. The surgeon should be in sympathy with and familiar with the problem. Most surgeons do not refuse an indicated operation, but apparently some surgeons do not agree that a person should be operated on for the good of the group in the absence of personal symptoms. Such surgeons can hardly be expected to do good carrier surgery. But, even with the personal point of view uppermost, these operations come under personal prophylactic surgery, as the organs are always chronically inflamed and the gallbladders usually contain stones.

In cholera the pathology of carriers is apparently identical with that in typhoid carriers, with the exception that there is some question as to the mechanism of gallbladder infection, whether it is through the portal circulation and bile or whether it is an ascending or lymphatic infection. The same principles in surgical treatment should hold in case of cholera, and the surgical treatment of carriers can be expected to be of even more value than in typhoid, as the disease has a more definite seasonal occurrence. In dysentery the evidence is not sufficient to warrant definite statements, but by analogy the same situation may also obtain.

SUMMARY AND CONCLUSIONS

1. So-called "urinary" typhoid carriers are really kidney carriers and can be cured by nephrectomy. An additional argument for operation is present if the infected kidney is functionless. One such case is recorded.

2. "Intestinal" carriers are really bile passage carriers of two kinds:

(a) Cases in which the gallbladder alone is infected. These can be cured by cholecystectomy. Four such cases are recorded.

(b) Cases in which the gallbladder and bile passages are both infected. In these cases cholecystectomy does not cure the carrier condition and the condition is incurable at present. Two such cases are recorded.

3. The surgical treatment of typhoid carriers, while not perfect, is the best available.

MUSTARD GAS*

E. K. MARSHALL, JR., Ph.D., M.D.

Associate Professor of Pharmacology, Johns Hopkins Medical School
BALTIMORE

One of the best known of all the war gases¹ and perhaps the most interesting is the so-called "mustard gas" or dichlorethylsulphid. This gas was first used by the Germans in July, 1917, and received its name from its smell, which resembles the odor of garlic or mustard. It is not a gas at all, but a high boiling, oily liquid, which vaporizes slowly in the air. It is a very poisonous substance and exerts a local action on the respiratory tract, eyes and skin, and a general systemic action when absorbed in sufficient concentration into the blood stream. In the concentrations of this "gas" which are present in the field, probably very little systemic action is generally noticed. The systemic action of the substance is of importance, however, as it leads us to a better understanding of the mechanism of action of the poison, and hence to an intelligent pursuit for a rational method of treatment.

DIFFICULTY OF DETERMINING TOXICITY

One of the first points which must be carefully determined in investigating a substance of this kind is its toxicity. It is important that this be determined very carefully for numerous reasons: (1) to learn what concentrations are dangerous in the field; (2) to ascertain how effective protective devices have to be to remove the "gas," and (3) to furnish a basis for accurate experimental work on treatment. This necessitates the determination of the toxicity of the substance in the form of vapor, and not by the ordinary method of administration by mouth, subcutaneously or intravenously. The simplest method of determining its toxicity in the form of vapor would appear to be to place animals in a gas-tight box and introduce a known amount of the substance in the form of vapor. But difficulties arise. The concentration is not accurately known unless chemical analyses of the air are made, and then it is found to be much less than that calculated from the amount of substance introduced, mainly because of condensation on the walls of the chamber, of absorption of the substance by the skin and the hair of the animals and, probably, in some cases, of decomposition of the substance by moisture in the air. Moreover, it is found that the concentration decreases markedly with time. Because

*Read before the Section on Pathology and Physiology at the Seventeenth Annual Session of the American Medical Association, Atlantic City, N. J., June, 1919.

*The experimental investigations on which this paper is based were conducted by the Pharmacological Research Section, Medical Division, Chemical Warfare Service, at the American University Experiment Station, Washington, D. C.

1 For description of gases used by the Germans, see Auld: J. Washington Acad. Sc. 8: 45, 1918.

of these factors, the figure used for the concentration is more or less guesswork. To overcome these difficulties, a chamber is used through which a continuous current of air, containing a known and constant amount of the poisonous vapor, is passed. In fact, the air in the chamber is changed once or twice a minute.²

Another point of difficulty is the great individual variation in the susceptibility of animals. This is probably greater than when the poison is administered subcutaneously or intravenously. It necessitates the use of a large number of animals in making a determination of the toxicity of a gas. Again, the toxicity for different species may vary, and as our ultimate aim is a knowledge of the toxicity for man, a great many different species must be used. If the toxicity is widely different for different animal species, it is hard to arrive at a conclusion as to the toxicity on man. In the case of mustard gas, determinations on dogs, rabbits, guinea-pigs, rats, mice, goats and monkeys have shown that there is no wide species variation as with some other gases. Hence, the figures obtained on animals will probably apply to man.

EXTREME TOXIC EFFECT

Without giving detailed figures, it may be said that this gas is an extremely toxic one. Five-tenths mg. per liter of air (or one part in 14,000) will kill an animal on an exposure of less than five minutes, while less than 0.01 mg. per liter (or about one part in 1,000,000) will prove fatal on eight hours' exposure. Death will not be immediate, of course, but will take place some days later. Concentrations smaller than the lethal ones will produce toxic effects.

For instance 0.0005 mg. per liter (or about one part in 14,000,000) will cause conjunctivitis on a prolonged exposure, and may incapacitate a man. About 0.002 mg. per liter (or about one part in 3,000,000) will cause a skin burn in a sensitive person on prolonged exposure. The reason why mustard gas has proved to be more an incapacitating gas than a lethal gas, under warfare conditions, is undoubtedly its very low vapor pressure. Very low concentrations are obtained in the field with this substance for any length of time.

SYMPTOMS AND SYSTEMIC EFFECTS

The symptoms which arise from exposure to mustard gas are now too well known to need detailed description.³ They consist essentially of local irritation of the upper respiratory tract, eyes and skin, giving rise to conjunctivitis and superficial necrosis of the cornea, hyperemia, edema, vesication, and later necrosis of the skin, leading to a skin lesion of great chronicity, and congestion and necrosis of the epithelial lining of the pharynx, trachea and bronchi. In animals exposed to high concentrations of this gas, vomiting and diarrhea, hyperexcitability and convulsions, and effects on the heart suggest an absorption into the blood stream and a systemic action.

Experiments demonstrate clearly that there is an absorption through the lungs of dichlorethylsulphid. When this substance is injected either subcutaneously or intravenously into a dog, the following symptoms make their appearance after a latent period: saliva-

tion; hyperexcitability and convulsions; vomiting and bloody diarrhea; a slow and irregular heart, which becomes rapid before death; muscular weakness, and finally, coma and death. Necropsy reveals a more or less intense congestion of the intestinal mucosa, which is frequently accompanied by hemorrhage into the lumen of the intestine. These effects on the heart, the gastro-intestinal tract and the central nervous system can practically all be observed in dogs poisoned by inhalation of high concentrations of mustard gas. This leaves little room for doubt that in high concentrations this gas is absorbed through the lungs and produces systemic effects in the body. Further proof of the absorption through the lungs is furnished by the detection of one of the decomposition products of mustard gas in the urine of gassed animals. On contact with water, mustard gas hydrolyzes very readily and gives rise to hydrochloric acid and dihydroxyethylsulphid:⁴

Dihydroxyethylsulphid was injected into a dog, and the urine was collected and examined for this substance. A positive test was obtained. This proves that the substance is excreted, in part at least, unchanged. The injection of dichlorethylsulphid was next tried and the urine found to contain the dihydroxyethylsulphid. The latter substance was then detected in the urine of animals which had been poisoned by inhalation of mustard gas.

MECHANISM OF ACTION

The latent period in the development of the effects of mustard gas either when inhaled or injected, suggests that the substance may be altered chemically in the body before exhibiting its characteristic effects. The simplest chemical change which the substance undergoes in the test tube is a hydrolysis into hydrochloric acid and dihydroxyethylsulphid. That this change also takes place, in part at least, in the animal organism is evidenced by the excretion of dihydroxyethylsulphid in the urine. The injection, however, of a completely hydrolyzed solution of mustard gas is followed by absolutely no symptoms. The dihydroxyethylsulphid has no irritating effect on the skin and is comparatively a nontoxic substance when injected intravenously. This decomposition product is, therefore, not responsible for the effects of mustard gas. Hydrochloric acid, the other product of hydrolysis, is not a very toxic substance. It can be injected in small doses without very much effect. The buffer system of the blood immediately neutralizes the acid, and the tissues are really never exposed to it. When the body is flooded with large doses of acid, however, death results. An acid reaction is incompatible with life. Both products of hydrolysis of mustard gas are readily soluble in water and sparingly soluble in organic solvents, while mustard gas is very sparingly soluble in water and freely soluble in organic solvents. The hydrolytic products have a low lipid solubility and would not be expected to penetrate cells easily, while mustard gas has a high lipid solubility and would probably penetrate cells readily.⁵ Its effects on the skin prove its power of penetration. Having penetrated into the cell, it would undoubtedly hydrolyze in

the aqueous phase of the cell. The liberation of free hydrochloric acid within the cell would produce serious results and might explain the effects of dichlorethylsulphid. To summarize, then, the mechanism of the action of dichlorethylsulphid appears to be:

1. Rapid penetration of the substance into the cell by virtue of its high liquid solubility.

2. Hydrolysis by the water within the cell, to form hydrochloric acid and dihydroxyethylsulphid.

3. Destruction by hydrochloric acid of some part or mechanism of the cell.

Accumulated knowledge of various other facts tends to substantiate this theory of the intracellular liberation of hydrochloric acid as the mechanism of the action of mustard gas.⁶ The ideal treatment for mustard gas poisoning would be to employ some nontoxic substance which would penetrate the cell and neutralize the effects of the hydrochloric acid. Efforts made in this direction have not been entirely successful.

It is interesting to note that all the war gases contain a halogen and can give rise to hydrochloric or hydrobromic acid on decomposition. One might, therefore, speculate on the possibility of the action of all war gases being due to the liberation of acid. At present, however, this is merely speculation.

In regard to the action of mustard gas on the skin, it is well known that some persons are more readily affected than others. We have been able to devise simple tests for determining the susceptibility of the skin of an individual to mustard gas. Without going into detail as to the methods used, I may summarize certain interesting facts which have been discovered. One man may be 600 times as susceptible to the action of mustard gas as another. Negroes, as a race, are far more resistant than white men. About 2 to 3 per cent. of white men are hypersensitive, while 20 to 40 per cent. are resistant. If a hypersensitive and resistant man are exposed to mustard gas, the former will undoubtedly receive severe skin burns, while the latter will easily escape them.⁷

Birth Rate of Whites During War Normal.—To ascertain whether the war affected the birth rate of Maryland and Baltimore, because of agitation regarding this subject abroad and elsewhere in the United States, Dr. Frederick V. Bentler, Halthorp, Md., of the Bureau of vital statistics, has compiled statistics covering the period from 1915 to July 1, 1919, inclusive, and the conclusions which the study of the figures presented revealed that the birth rate, whatever has happened abroad, has not been affected appreciably in Maryland. On the contrary, births in 1918 and thus far in 1919 have been normal. The only doubt which might exist that they may perhaps make the rate appear a shade less than normal lies in the inability to estimate properly the growth of population in the state during those months of the war period, that is, the growth from outside sources—from migration here from other sections of the country. Just what this has been no one seems to know with any certainty, but that it has not been sufficient to weigh heavily on the side of diminution of birth rate is a generally accepted fact among those who have given the matter serious attention. In 1918 the death rate exceeded the birth rate, a condition which had not been noted before since the health wardens have been tabulating the returns. This was caused by the influenza epidemic and ailments incident thereto and it is reflected in the early returns of 1919, but the present year, unless there is a recurrence of the malady, will about measure up to other years in proportion to the population.

POISONING WITH THE LETHAL WAR GASES*

PHYSIOLOGY AND EXPERIMENTAL TREATMENT*

FRANK P. UNDERHILL, Ph.D.

Professor of Experimental Medicine, Yale University School of Medicine
NEW HAVEN, CONN.

The most important members of the group of lethal gases are chlorin, phosgen and cloropicrin. These substances are alike in that they act on the respiratory tract, producing edema and congestion. Chlorin acts with extreme rapidity. The toxic action of phosgen is slower, probably because, to produce its effects, it must undergo chemical change. This fact has earned for phosgen the name of having a delayed action. Cloropicrin appears to stand somewhere between chlorin and phosgen, both in regard to the type of influence provoked and in the rate of production of intensive edema.

From an extensive investigation, on dogs and goats, of the acute effects of gassing, it is quite evident that the detrimental influence of these gases is confined to the respiratory tract and that all other effects must be regarded as secondary, since it has been impossible to determine the absorption of these gases into the blood stream. Exposure to them results in a variety of changes in the organism, in addition to the development of pulmonary edema. Thus, gassing has a definite influence on the respiration, heart beat, temperature, concentration of the blood, the water content of the lungs and other tissues, the chlorid content of the blood and tissues (with resulting changes in chlorid excretion by way of the kidney), the number of red and white cells of the blood and the respiratory function of the blood, leading to dyspnea and partial asphyxia. Acidosis is present at times, and there is a distinct influence on protein metabolism.

When one attempts to correlate these various effects, the task at first seems well nigh impossible. Closer inspection, however, brings to light one significant feature, namely, changes in the concentration of the blood. Viewed from this standpoint, the picture presented by a typical lethal gas, namely, phosgen, shows that acute gas poisoning may be divided into three stages.

STAGES IN PHOSGEN POISONING

In the first stage, which lasts from five to eight hours, there is usually a very significant dilution of the blood. In this period, pulmonary edema is developing. In the first part of this period the temperature may fall markedly; in the latter part of the period there is a greatly accelerated pulse, accompanied by a rise in temperature considerably above the normal.

The second stage, which reaches its maximum between the fifth and twenty-fourth hours, is characterized by a very marked concentration of the blood. In this period the temperature may be well maintained, or there may be a distinct drop below normal. If the temperature is well maintained, the condition of the individual is considered good. On the other hand, if the temperature suddenly falls, the outcome is usually fatal.

* Read before the Section on Pathology and Physiology at the Seventieth Annual Session of the American Medical Association, Atlantic City, N. J., June, 1919.

The third stage is characterized by a readjustment to normal conditions with respect to both concentration of the blood and temperature.

AN INTERPRETATION OF GAS POISONING

The interpretation which may be placed on the different stages of phosgen poisoning is as follows:

In the first stage there is marked dilution of the blood. There are at least two ways in which this dilution may be explained. In the first place, it may mean an increased blood volume, the excess fluid finding its way into the blood from the tissues in response to the strong irritation stimulus exerted by the gas on the respiratory tract. Or secondly, a diluted blood would result if the red cells were removed in part and deposited in some organ or tissue. In the present investigation no studies have been made to determine actual changes in blood volume. Reports by Eyster and Meek, however, who have made such estimations, tend to the conclusion that in the stage of phosgen poisoning under discussion, blood volume is not increased, and they account for the dilution of the blood on the hypothesis that red cells are stored in the lungs, at least temporarily. Whichever explanation is correct, it is certain that during this first stage two features may be quite prominent, namely, edema of the lungs and dilatation of the heart. Edema can be explained very readily on the hypothesis of increased blood volume, and it is also possible that such a condition might lead to a dilated heart. On the other hand, the deposition of corpuscles in the lungs, by causing an obstruction in the circulation, would lead to a dilated heart. The relatively large transport of fluid to the lungs during this period is, however, not so easily explained by this hypothesis. Whichever hypothesis is accepted, edema of the lungs prevails, and there may be a dilated right heart.

In the second period, edema has reached its maximum development, and here, also, blood concentration is at its height. The latter state is undoubtedly induced by the withdrawal of fluid which finds its way into the lungs. During the interval of blood concentration, the blood volume is definitely decreased, and the heart may be noticeably diminished in size (Eyster). This, presumably, would result in a decreased efficiency of this organ and lead to an inadequate circulation. Later, when the blood resumes its normal degree of concentration, normal heart action is reestablished.

The development of edema induces a mobilization of chlorids in the lungs at the expense of the chlorids of the blood, the lowered chlorid content of which may be explained in part by loss of chlorids through the kidneys, since at this period the output of chlorids in the urine is appreciably augmented. Later, during the second stage, the chlorids of the lungs reach a maximum, the blood content is not called on, and, therefore, an approximately normal blood chlorid content may be found, which is maintained thereafter. This chlorid retention by the lungs coincides with the fact that on the second day of phosgen poisoning the urinary excretion of chlorids is usually below normal. The period of readjustment now follows, during which edema subsides in the lungs, and presumably both fluid and chlorids are demobilized by the lungs and find their way into the blood. The excess of chlorids over the normal in the blood is eliminated through the kidneys. This circumstance would account for the large output on the third day after gassing.

The changes in oxygen capacity, erythrocytes and hemoglobin follow the curve of alterations in blood concentration throughout the entire course of phosgen poisoning, which might well be anticipated. The oxygen content of arterial blood shows, in general, relatively unimportant changes, whereas that of venous blood progressively diminishes throughout the first and second periods of phosgen poisoning. This may be explained in the first period by the fact that the blood is diluted, and, in the second period, is undoubtedly caused by the longer contact of the blood with the tissues, induced by an inefficient circulation.

The respiratory changes are correlated with the impaired respiratory functions of the blood, such as lowered oxygen content and incomplete saturation of the hemoglobin with oxygen.

In the first stage, the decreased heart rate may be explained best perhaps on the hypothesis of nervous inhibition. The later rapid pulse is directly induced by the viscous character of the blood, which causes oxygen want. Although specific data are lacking, it appears quite evident that there is a distinct fall of blood pressure. One may assume a direct relationship between the heart's efficiency and temperature. Thus, in the first part of the first stage, the heart action is slow, there is inefficient circulation, and the temperature falls. Later, the greatly accelerated pulse is accompanied by a rise in temperature far above the normal. From this it would appear possible that the heart has temporarily overcompensated, resulting in an efficiency of the circulation above the normal.

Now follows the stage of concentration of the blood. This concentrated blood is, without doubt, more difficult to circulate through the body, and, if the heart is doing only its normal work, there will be, as a result of the thickened blood, a circulation of less than normal efficiency; and such a condition apparently results in a falling temperature. In case the heart responds with a much higher rate during the period of concentration, so that even with the thickened blood it appears that a circulation of close to normal efficiency is being maintained, it will be found that the temperature is also well maintained.

In the animals which are less seriously affected, and in which only a slight edema of the lungs develops, with a consequent slight loss of fluid from the blood, it will be found that the temperature is well maintained, provided the heart rate is normal. Even in such cases, however, the continuous, even though slight, loss of fluid from the blood will eventually result in a concentration of the blood which will bring the circulation below normal efficiency, even with a high pulse rate; and the temperature will slowly drop until, at about the twenty-fourth hour, it is about 1 degree Centigrade below the normal. On the other hand, in the animals which are seriously affected, the blood concentrates very rapidly. The heart, even though the rate is maintained far above normal, is nevertheless not able, apparently, to maintain a circulation of normal efficiency; the temperature drops very rapidly, and the animal dies within less than twenty-four hours after gassing.

In brief, then, it seems plausible that the temperature is directly related to the efficiency of the circulation, and this in turn is determined, in part at least, by the concentration of the blood and by the pulse rate.

This view seems to be further strengthened by the results obtained from a study of animals gassed with chlorin and chlorpicrin. In both of these cases there is, in general, a state of concentration of the blood beginning immediately after gassing. Only in rare instances does dilution of the blood occur, and then it is only for a short time. From the first, then, in animals poisoned with the last named gases, there obtains a condition in which the blood is above normal in concentration, and, in correspondence with this, the temperature remains below normal; and the more seriously the animal is affected and the greater the concentration of the blood, the greater will be the fall in temperature.

Phosgen poisoning has been considered in detail, since it is unique in showing among its effects the initial stage of dilution of the blood. At times, chlorpicrin presents a similar stage, but the interval is never so pronounced in length, nor the dilution in degree, as obtains in phosgen poisoning. Usually a preliminary dilution period is lacking. It is this period that undoubtedly gives to phosgen the distinction of possessing a so-called "delayed action." Chlorin gas rarely, if ever, causes a period of blood dilution. In general, if one should consider the changes in blood concentration outlined for phosgen, minus the initial dilution period, the remaining curve would represent fairly accurately the alterations occurring in the blood in both chlorin and chlorpicrin poisoning. This would, of course, entail differences in time relationships; but, under the conditions noted, the changes in blood concentration, in cases of chlorin and chlorpicrin poisoning would be accompanied by the same general type of effects which is produced by phosgen. Under these circumstances, it appears superfluous to recite further the correlation of the effects of chlorin and chlorpicrin poisoning.

CAUSE OF DEATH

It is usually assumed that pulmonary edema is the cause of death in gas poisoning. While it is true that pulmonary edema and changes in blood concentration are intimately associated in gas poisoning, the edema being the cause of the concentrated blood, nevertheless, the direct cause of death is the extreme concentration of the blood rather than the presence of fluid in the lungs. Death is caused by something more than simple inability of the blood to absorb oxygen, by something more than a physical obstacle in the lungs. It is quite logical, therefore, to assume that blood concentration is immediately responsible for death. Blood concentration means a failing circulation, an inefficient oxygen carrier, oxygen starvation of the tissues, fall of temperature and, finally, suspension of vital activities.

The whole aim of treatment in acute gas poisoning has been to prevent blood concentration, or else to restore it to a level more nearly normal. When this is accomplished, the individual survives in spite of the fact that the lungs may be very edematous. If it is recognized that changes in the concentration of the blood are responsible for death and that treatment for gas poisoning consists in the restoration of the blood concentration to a level more normal, then it is apparent that there should be criteria which shall give indication of the animal's condition. Such criteria are to be found in changes in temperature and in hemoglobin estimations. It may be stated that either criterion may be used alone, but that greater dependence may be placed on the combination of the two.

TREATMENT

The principle of the method of treatment of acute gas poisoning consists of venesection in the period of blood dilution and of the introduction of fluid into the body during the period of blood concentration. Venesection is practiced as soon as practicable after gassing, to the extent of approximately 0.5 per cent. of the body weight. Hemoglobin and temperature changes are then observed at one-half hour intervals. So long as the temperature remains normal and the blood concentration does not diminish, further treatment is not necessary. When, however, the temperature rises rapidly and a fall in blood concentration occurs (the two changes take place simultaneously), a second venesection of 0.5 per cent. of the body weight is practiced. This procedure may be repeated a second time, that is, until blood to the extent of 1.5 per cent. of the body weight has been withdrawn. In a large majority of cases there is needed no further treatment, and practically every animal survives.

If, in spite of intensive treatment in the first stage, the blood becomes markedly concentrated, and a notable fall in temperature takes place, the condition must be considered very serious, and if the animal is left untreated it will surely die. At this point, of course, infusion of a solution is indicated. The essential feature in the stage of blood concentration is to diminish, if possible, the degree of concentration, and it has been found by experience that it matters little how this is done. Thus, this purpose may be accomplished by the infusion of salt solution, by oral administration of water, or even by intraperitoneal injection of salt solution. Probably one-half the animals in a serious condition in this stage of blood concentration may be saved by following either procedure.

Since edema and a highly concentrated blood lead to deficiency of oxygen in the blood and tissues, the problem of the relation of oxygen administration to the treatment of gas poisoning is presented. It will suffice here to state that oxygen treatment alone in gas poisoning does not save life. This follows from the fact that oxygen administration does not change the concentration of the blood, which is the direct cause of death. When, however, the concentration of the blood is restored to a more nearly normal condition, the addition of oxygen administration to the treatment is of obvious benefit, since under these circumstances the blood regains its normal respiratory functions.

With respect to the treatment of chlorin and chlorpicrin poisoning, the principles enunciated for phosgen hold true. While the principles are the same, there is a difference in the time of application, for, in general, in chlorin and in chlorpicrin poisoning the initial stage of dilution of the blood is lacking. With phosgen, early bleeding and delayed infusion are advocated. With chlorin and with chlorpicrin, early bleeding and early infusion are imperative. Moreover, in chlorin poisoning there is evidence of a significant acidosis; hence, the administration of sodium bicarbonate by mouth is advocated, in addition to the treatment outlined for phosgen. As a result of the treatment outlined, the recoveries are increased threefold.

Aside from the interest which attaches to these principles in the treatment of gas poisoning, they may be of special significance in other pathologic states in which inflammation or edema are especially prominent. A recognition of the salient features attendant on

changes in the concentration of the blood in various abnormal conditions would necessitate new points of view with respect to treatment. It is hoped that in the near future an opportunity may be afforded whereby an extensive investigation may be made with this idea in mind.

CHRONIC LESIONS OF THE RESPIRATORY TRACT

INITIATED BY THE INHALATION OF IRRITATING GASES*

M. C. WINTERNITZ, M.D.
NEW HAVEN, CONN.

The majority of the gases which have been utilized in the recent war owe their efficiency to their irritative and escharotic action on the respiratory tract. This action causes an inflammatory edema, which is followed by a cellular exudate, both in the upper air passages and in the pulmonary parenchyma. While the highest mortality occurs in the acute, or edema, stage, a second peak in the mortality curve is encountered with the pneumonia process. The type of the latter inflammatory reaction is largely determined by the extent of the primary destruction. Many gases produce such deep seated necrosis that if death does not ensue in the acute edema stage or at the height of the pneumonia process, organization of the exudate within the alveoli and, more frequently, of that in the bronchioles, may occur. The contraction of the scar may lead to serious and progressive mechanical difficulties, not only with the ingress and egress of air into the alveoli, but also with the pulmonary circulation, and ultimately with the aeration of the blood in the lungs. Chronic suppurative inflammatory processes, too, may persist, especially in the bronchi, with a typical picture of a tubular, or even of a saccular, bronchiectasis or bronchiolectasis.

The various gases of the respiratory irritant group have a similar action, but differ in the localization and extent of their necrotizing effect. A brief review of the pathology of mustard gas, chlorin and phosgen will emphasize this difference.

Not only does mustard gas, in lethal concentrations, destroy the lining of the entire bronchial tree, but its necrotizing action involves the lung itself. In more dilute form, it produces necrosis of the epithelium of the trachea, which, however, becomes less marked toward the finer ramifications of the bronchi. The gas seemingly spends itself in the upper air passages. It either does not reach the bronchioles and alveoli, or it reaches them in such a diluted or changed state that the occurrence of chronic pulmonary lesions after this gas is rare.

After chlorin inhalation, there is also an injury to the lining of the entire respiratory tract, even to the ducti alveolares and to the alveolar walls themselves. The epithelium is blistered, but the necrosis in the trachea and in the larger bronchi is not as deep and extensive as it is with mustard gas. Probably on account of its less efficient corrosive action, the injury of the pulmonary parenchyma, not so severe even in the acutely fatal cases, results more frequently in

chronic lesions, which may cause death long after the initial symptoms have passed.

Phosgen has the least severe action on the respiratory tract, but in its wake the most frequent and persistent lesions are left. Organization of bronchiolar and peribronchiolar exudates, with obliteration or dilatation of the lumina of the bronchi, leads naturally to serious and progressive obstruction to the passage of air and the circulation of blood in the lungs.

That there is immediate death of the epithelial lining cells of the respiratory tract after exposure to these poisonous gases may be demonstrated with vital stains. Within two hours after inhalation of chlorin, dogs whose circulation had been previously heavily laden with trypan blue show deep blue nuclei in the mucous membrane of the trachea, bronchi and bronchioles, and even a staining of entire alveolar walls.

This injury is the anatomic expression of the destruction of the normal protective mechanism of the upper respiratory tract, and is followed by an invasion into the lung of the bacterial flora of the mouth. This has been demonstrated repeatedly by mouth cultures before exposure to poisonous gas, and by subsequent cultures, not only of trachea and bronchi, but also of the lung itself.

It has been shown that the high mortality in the most acute or edema stage is not due to the accumulation of fluid within the air sacs. Pulmonary edema must be regarded as the expression of a more deep seated process, and in itself is probably never a satisfactory explanation for death. When death does not terminate the process, the inflammatory exudate which supervenes is readily explained by the presence of large numbers of bacteria that find in the trachea and lung, injured by the action of the gas, a fertile medium for development.

Interesting as these two stages may be, it is most important to recognize that the primary escharotic action of these gases frequently leads to much more extensive lesions of the respiratory tract than are usually encountered. Even though the animal may survive, the necrotizing tracheitis, bronchitis and pneumonia characteristic of the acute stages do not allow restoration to normal of the respiratory tract. The initial damage is followed by organization, which may be sufficiently extensive after mustard gas inhalation to produce stenosis of the larynx or trachea. After chlorin, phosgen, superpalite, cyanogen bromid, chlorpicrin, etc., a progressive fibrosis with obliteration or dilatation of the smaller air passages may result. This occurs not only when the acute effects of the gas have been manifest, but, with the phosgen group especially, it may follow even when no marked expression of acute damage has been observed. With bronchiectasis, metastatic infection in the parenchymatous organs has been noted; but in general the changes, both during the life of the animal and at necropsy, are characteristic of this condition. With obliteration of the smaller air passages, pulmonary emphysema and atelectasis lead to a progressive respiratory disturbance which is much more manifest with physical exertion.

For the present, the chronic or residual lesions, after inhalation of these poisonous gases, are decidedly the most important. It seems possible that graded respiratory exercises may prevent the contraction of the scars in the finer ramifications of the bronchi during the period of their formation and, in this way, aid at least, in the amelioration of the distressing condition which may follow.

ABSTRACT OF DISCUSSION

ON PAPERS OF DRs. MARSHALL, UNDERHILL AND WINTERNITZ

DR. A. M. PAPPENHEIMER, New York: I should like to ask Dr. Marshall if he came to any conclusion as to whether the intestinal lesions following the injection of mustard gas were due to the elimination of the gas by the intestine. Lesions of the alimentary tract were found in a certain proportion of the human cases, sometimes erosions of the stomach, sometimes hemorrhages in the small intestine; but we could not decide whether they were an essential of the pathologic picture of mustard gas poisoning. As regards the possible systemic toxicity in the human, there are certain suggestive observations. There was a group of cases in which the burns of the skin or of the respiratory tract did not seem to account for the severity of the symptoms, cases with widespread pigmentation, great prostration and apathy, low blood pressure and curious mental symptoms. Another bit of evidence in favor of the systemic effect is the marked leukopenia present in severely gassed patients, as described by Zinz and Krimlhaar, and observed also after intravenous injection in rabbits. In regard to the experimental methods of treatment brought out by the work of Dr. Underhill, there is unfortunately one factor which complicates their application in the human cases of phosgen poisoning, that is the early onset of bacterial infection. We did not have an opportunity to examine material from a large series of phosgen cases, but of four acute cases, the patients dying within twenty-four hours after gassing, several manifested even at that time a widespread streptococcal invasion of the lungs.

Dr. Winternitz's paper is of special importance in its emphasis on the permanent changes in the respiratory organs, which may develop after gassing. He has described in detail the late results of phosgen poisoning, but I am sure the changes after mustard gas poisoning must be equally important. Although many detailed studies have been made of early cases of mustard gas poisoning, the one practical question which remains now is to find out to what extent permanent lung injury is to be expected and how far that is going to explain the persistent disability in many of the gassed soldiers. In addition to the not infrequent development of bronchioectases and bronchiectases, we have been struck by the very regular occurrence in the later mustard poisoning cases, of a widespread metaplasia of tracheal and bronchial epithelium into the squamous cell type. We are not yet able to state whether this is a permanent change, but as a possible predisposing factor in favoring the onset of secondary bacterial infections, it seems to be worth noting.

Dr. E. R. LE CONTE, Chicago: I wish to ask Dr. Marshall about the hemorrhages observed in the stomach and bowel and as to whether they might be explained by the changes in blood volume and circulation, and, therefore, whether they may be, perhaps, in a small degree analogous to infarction hemorrhages.

Dr. W. M. L. COPLIN, Philadelphia: One of the important things to remember is the influence of desquamation and deciliation. These patients come in at varying periods after gassing, some after a week, at which time the ciliated epithelium has disappeared from the trachea and cannot be demonstrated post-mortem even in the bronchi. I have seen gangrene in these lungs twenty-six days after gassing and I have seen some tracheal mucosa resemble the dense skin of psoriasis with superposed eczematous surface. The mucosa would break in fissures when the bronchus was opened, so that the passage has not only lost the normal method of removing contained discharges by means of cilia, but the rigidity of the tube is such that the coughing mechanism is destroyed even assuming that hecsthesia still persists or is possible. A very interesting symptom is the paroxysmal attacks that come on any time from days to weeks after gassing. These patients will sometimes be going about the hospital grounds when they are seized with intense dyspnea, air hunger and cyanosis; occasionally a grayish pallor is present. This may be preceded by or follow cyanosis and occasionally is terminal only. One naturally thinks that

these are instances of recurring edema, which no doubt is a factor, but in reality they are simply cases where desquamation, with packing of pus and cell detritus causes bronchial obstruction, with possibly some element of spasm. I have seen the bronchus completely filled with necrotic masses. If the changes are not too great and infection does not supervene, some occluded tracks go on to organization. Intestinal ulceration may be present; pyloric or duodenal ulcer is not seen frequently; ulcers in the small intestine, duodenum and stomach are not unlike those associated with extensive burns of the skin. We cannot help thinking of the same explanation, because for a week or ten days the appearance is not what is observed after severe burns. I do not believe that severe destructive lesions in the bronchi will ever reciliate. It is surprising to what degree clinical recovery may progress.

Another interesting feature that we had an opportunity to observe is the susceptibility of gassed patients to respiratory irritants. There is a hypersensitivity of the bronchial mucosa. Often these patients cannot endure the least trace of smoke. I believe that the irritability occurs in practically every instance. One other point is the change in the walls. One may see areas in the mucosa fairly well preserved, and immediately adjacent or extending in irregular plaques, usually in the long axis of the tube, there is an area of extensive necrosis with sometimes a definite ulcer and sometimes with a hard, breakable mucosa. I think Dr. Le Conte's explanation that it might possibly be due to infarction, is worthy of acceptance. The intense hemorrhage in the intestine seen in some of these cases, resembles acute hemorrhagic septicemia, and it is quite possible that it is due to infection; certainly a few weeks following injury the lungs are often found as full of bacteria, almost, as are lungs that have been retained post-mortem outside the body. I saw very few cases of gassing in the early stages, but never one in which bacteria were not abundant in secretions and pulmonary tissue. In the early hours, certainly within twenty-four hours, the bacterial invasion is frequently streptococci, often intense, and more gas bacilli may be found in these lungs than in those of patients who have died of gas gangrene.

Dr. H. E. ROBERTSON, Minneapolis: I have had the opportunity of observing both clinically and at post-mortem the skin reactions in gassed soldiers who had a varying amount of pigmentation of the skin. I can confirm Dr. Marshall's observation that the negroes are comparatively insensitive. We had side by side in one hospital negro troops and white troops, who had suffered about the same exposure and the whites were burned more severely than the negroes. While the negroes were comparatively free from skin burns, their respiratory tracts were as severely affected, if not more so, than those of the whites. We investigated the question of relative susceptibility between dark and fair skinned individuals, but we could not determine that the blonde types are more susceptible than the brunette types. May I ask Dr. Marshall how he believes the negro's pigmentation acts as a protector of the skin? Also is there any protection against mustard gas given by the darker skin of white people? I confirm Dr. Pappenheimer's observations in regard to bacterial invasion of the respiratory tract. I have never seen a case where the bacteria were not numerous. We found an interesting series of cases in which all evidences of intoxication had disappeared after ten or twelve days the patients were apparently progressing toward convalescence. Some of these patients were then moved to the ambulatory rooms in the wards and were pronounced on the road to recovery. These patients would suddenly develop a bronchitis, bronchopneumonia and die. At the time of the post-mortem in these cases it was clearly evident that the lesion produced by the gas had not cleared up, and why they should show such marked improvement physically and mentally when their bronchi were in such dangerous condition, I cannot understand, except that there is a return to normal of the blood. This secondary infection, because it was a secondary infection which took these patients, was generally extremely virulent. Streptococci, pneumococci and often influenza bacilli were found.

Dr. W. M. L. COPLIN, Philadelphia: Regarding this question of skin susceptibility, I know one officer who had a severe gas burn involving most of his face outside of the shaven beard line. I asked what his explanation was regarding the escape from burn of the shaven portion of the face; he said he had difficulty in shaving, his skin was tender and he was in the habit of using some sort of ointment; he did not know what the ointment contained. I was wondering if some constituent of the ointment possibly might have acted as a protective against these gasses.

Dr. FRANCIS CARTER WOOD, New York: I suppose no one has seen the early chlorin cases. What about it in experimental animals? Is the infection likely to occur in animals the same as pure chlorin gas poisoning as regards bacterial invasion?

Dr. W. M. L. COPLIN, Philadelphia: There are instances of pigmentation occurring in men who had never been gassed sufficiently to blister, or who did not know they had been gassed. It would be interesting to know whether the pigment of these men acted as a protector against irritation. That would warrant some investigation on pigment producing a protective influence independent of the local action.

Dr. E. K. MARSHALL, JR., Baltimore: In regard to the intestinal lesions of mustard gas, I have no experiments that would tend to substantiate any definite explanation. It is true that the intestinal lesions in dogs vary from a simple congestion of the intestine with few hemorrhages to a complete hemorrhagic condition of the duodenum and cecum. In regard to these lesions being due to changes in the blood, as Dr. Le Count suggests, or to secondary changes brought about by gas poisoning, it seems somewhat improbable in that they do not occur with any of the other gases, chlorin, phosgen, etc., which produce the same changes in the blood which mustard gas does. One might possibly expect that the mustard gas is secreted in the bile. We made tests in the bile of animals but have been unable to demonstrate the presence of mustard gas. Of course, it is possible that the mustard gas might be excreted through the cells of the intestines. No proof is at hand, however. In regard to the question of Dr. Robertson about the skin reaction and the explanation for it, I have an explanation which some data substantiate. The explanation for the conditions in the skin and the susceptibility is based on the following observations: First, it has been found that even a half hour after mustard gas is applied to the skin, if the skin is washed and scrubbed with an organic substance like kerosene in which mustard gas is soluble, the burns can either be prevented or reduced in severity. This shows that you can draw out the mustard gas from the skin a half hour after it is applied. If one covers the area with a glass cap so as to prevent evaporation of the mustard gas a much more severe burn results. The fact is that the sensitive man absorbs more gas than the nonsensitive man absorbs. We can make a definite exposure on the arm of the sensitive man and immediately after exposure apply the arm of the resistant man and the sensitive man will not burn, whereas the resistant man will. In other words, the resistant man can extract the gas from the sensitive man. We have come to the conclusion that sensitivity depends on the amount of fat and lipoids present in the skin. In a resistant man the gas is first absorbed in the fats and lipoids, there being a large reservoir of fats and lipoids in his skin. It is slowly evaporated and slowly carried inward into the cells where the damage is done. The transfer is so slow that there is never in the cells a concentration above the threshold. The sensitive man having a smaller amount of fats and lipoids is more apt to be damaged by the gas. In answer to Dr. Coplin's question, I think that is quite possible. You can get quite a severe burn with mustard gas which in some instances will not cause any pain and which will lead to pigmentation.

Dr. FRANK P. UNDERHILL, New Haven, Conn.: With respect to the first question on the treatment of lethal gas poisoning and the difference between the acute attacks and attacks of infection in the human cases, the same holds true in animals. Just a few hours after gassing you may have this same type of infection. The type of treatment which we

outlined is effective only when the individual has been received shortly after gassing. If ten, twelve or fifteen hours have elapsed previous to any attempt at treatment, then this treatment is quite unsatisfactory. At the time the armistice was signed attempts were being made to facilitate transportation to the gas hospitals so that treatment could be obtained earlier than had hitherto been possible. In answer to Dr. Wood's question, I will say, no.

New and Nonofficial Remedies

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

W. A. PUCKNER, SECRETARY.

COLON BACILLUS VACCINE (See New and Non-official Remedies, 1919, p. 283).

Fred I. Lackenbach, San Francisco.

B. Coli Bacterin (Special Bacterial Vaccine No. 12).—Marketed in 10-Cc. vials, each cubic centimeter containing 5,000 million killed *Bacillus coli*.

GNONOCOCCUS VACCINE (See New and Nonofficial Remedies, 1919, p. 285).

Fred I. Lackenbach, San Francisco.

Gonococcus Bacterin (Special Bacterial Vaccine No. 9).—Marketed in 10-Cc. vials, each cubic centimeter containing 1,000 million killed *Gonococcus*.

MIXED BACTERIAL VACCINES (See New and Non-official Remedies, 1919, p. 296).

Fred I. Lackenbach, San Francisco.

Staph-Aene Bacterin (Special Bacterial Vaccine No. 6).—Marketed in 10-Cc. vials, each cubic centimeter containing 500 million killed *Staphylococcus albus*, 500 million killed *Staphylococcus aureus*, and 50 million killed *Bacillus aene*.

PERTUSSIS BACILLUS VACCINE (See New and Non-official Remedies, 1919, p. 287).

Fred I. Lackenbach, San Francisco.

Whooping Cough Bacterin (Special Bacterial Vaccine No. 14).—Marketed in 10-Cc. vials, each cubic centimeter containing 2,000 million killed *B. Pertussis*.

STAPHYLOCOCCUS VACCINES (See New and Non-official Remedies, 1919, p. 289).

Fred I. Lackenbach, San Francisco.

Staphylococcus Bacterin (Special Bacterial Vaccine No. 1).—Marketed in 10-Cc. vials, each cubic centimeter containing 2,000 million killed *Staphylococcus albus*, 2,000 million killed *Staphylococcus aureus*, and 1,000 million killed *Staphylococcus citreus*.

STREPTOCOCCUS VACCINE (See New and Nonofficial Remedies, 1919, p. 291).

Fred I. Lackenbach, San Francisco.

Streptococcus Bacterin (Special Bacterial Vaccine No. 10).—Marketed in 10-Cc. vials, each cubic centimeter containing 1,000 million killed *Streptococcus*.

TYPHOID VACCINE (See New and Nonofficial Remedies, 1919, p. 292).

Fred I. Lackenbach, San Francisco.

Typhoid Bacterin (Special Bacterial Vaccine No. 17).—Marketed in 10-Cc. vials, each cubic centimeter containing 1,000 million killed *B. Typhosus*.

Typhoid-Paratyphoid Bacterin (Special Bacterial Vaccine No. 18).—Marketed in 10-Cc. vials, each cubic centimeter containing 1,000 million killed *B. Typhosus*, 750 million killed *B. Paratyphosus*, "A", and 750 million killed *B. Paratyphosus*, "B."

TETANUS ANTITOXIN, CONCENTRATED (See New and Nonofficial Remedies, 1919, p. 266).

Eli Lilly and Co., Indianapolis, Ind.

Tetanus Antitoxin—For Human Use: Purified, Concentrated (Globulin).—Marketed in syringes containing 1,500 and 5,000 units; in ampules containing 10,000 units, with apparatus for injection.

LEONARDO DA VINCI AS ANATOMIST (1452-1519)

When Leonardo da Vinci died (May 2, 1519) his anatomic notes and sketches passed by will to his faithful friend Melzi who, while he lived, guarded them as his most precious possessions; but unfortunately this reverence did not pass with them to his heirs. Yet, notwithstanding their extensive, roundabout, and still in large degree untracked travels, a very large part of Leonardo's anatomic manuscripts and drawings at last found safe abodes and became available for study and reproduction under favorable conditions.¹ How much has been lost will never be known. The quadri-centennial anniversary of Leonardo's death has brought out a number of articles² in which his work, particularly in anatomy and physiology, is discussed in the light of the latest investigations that anatomists, historians and linguists have made of it.

It appears to be established beyond any question of doubt that Leonardo commenced to dissect when he was about 37 years old in the hospital of Santa Maria Nova in Florence, that he continued this work in Milan, and that he dissected in Rome in 1513, when he was 61 years old, at which time Leo X forbade further work of that kind. It is stated that in all he dissected more than thirty bodies of men and women at various ages, besides various animals. Nor is there any longer any question about the absolute originality and complete independence of his anatomic work, which he carried far beyond the requirements of anatomy as pertaining to art. This is shown in the remarkable circumstance that he paid more and closer attention to the internal organs than even Vesalius or the other anatomists of that period. What interest has the artist in the cerebral ventricles, the internal arrangement of the heart, the course of the deeper nerves and vessels? It was a great love of anatomic and physiologic investigation, of science, that led him to work on and on through the years, steadily, no doubt, with poor illumination

and under many other difficulties, but to what amazing results!

Hopstock, one of the editors of Leonardo's Windsor manuscripts,³ himself an anatomist, after a careful review of all the published manuscripts, gives in essence this estimate of Leonardo as anatomist:

No one before him dissected so many bodies and no one understood the results of his dissection so well as he; no one before him represented in drawings the muscles, vessels and nerves as they are, which he did; no one before him knew the heart so well, but whether he understood the circulation, or thought he had a definite idea of the correct explanation of the circulation of the blood, remains doubtful. He was the first to describe the uterus as an organ with one chamber, to represent correctly the skeleton, to inject vessels with a solidifying mass, to make casts of the ventricles of the brain, to practice serial sections. As revealed by the notes, which cover a period of thirty years, and his marvelous red chalk drawings and impromptu sketches by the side of the dissected body, his work throughout is characterized by an almost uncanny accuracy, deep physiologic insight, untiring zeal, and an unflinching sense of the beautiful.

The painter of "Mona Lisa" and "The Last Supper" is the first great scientific anatomist, and yet, although he accomplished so much toward a correct understanding of the human body, his work was destined to have no tangible, traceable influence on the immediate development of anatomy and of medicine, because it was not to become known generally until many generations had passed and then only through fragmentary records. Van den Broek² points out that Leonardo's work in other sciences also remained sterile in the same sense as his work in anatomy. He is said to have studied the question of aviation over many years and to have declared that the flying machine must be built like the body of a bird so that the aviator "can balance himself and move through the air like a big bird, to the everlasting glory of the nest where he was born."

As further examples of the scope of his interests may be mentioned his studies of plant life, his interpretation of the sea shells on the mountain tops around Florence, and then the note in large letters on one of his sketches: "The sun does not move." A child of free love, disinherited, disliked by his stepbrother, and often misunderstood, Leonardo, after four hundred years, is taking his right place in history as one of the most gifted of men and as one of the most versatile and original of investigators. Perhaps the more remote effects of his work in illustrating the capacity

1. On the present state of Leonardo's manuscripts, one may consult Kuhn, A. C. *Leonardo da Vinci and His Anatomical Studies*, Baltimore, Md., H. S. Harter, 1916, 1916.

2. Hopstock, H. *Anatomy of Leonardo*, North Mag. C. Legevendenski, 1918. Van den Broek, A. J. P. *The Work of Leonardo da Vinci*, Utrecht, The Netherlands, 1917, 1918.

3. Under the name of Fugli A and B, Sabroshnikoff and Pinnati in 1908 and 1901 published sixty of the anatomic manuscripts of Leonardo known as the Windsor manuscripts. Fugli A and B contain facsimiles of about 400 drawings with transcription of the notes (Leonardo used mirror writing), and French translation. The rest of the Windsor manuscripts (190) with facsimiles of some 1,050 drawings with transcription and English and German translations have been published by Vangensten, Fomlin and Hopstock under the title *Quaderni d'anatomia*, I-VI, Christiania, Trondheim, 1911-1916.

of the human intellect, when directed to intensive effort by self-control and love of nature, will make up for the lost chance to influence the earlier development of science.

ARE THE CAPILLARIES CONTRACTILE?

In ultimate analysis, the nutritive functions of the tissues are closely dependent on the capillary circulation within them. It is only through the medium traversing the smallest vessels of the circulatory system that the living cells secure the oxygen and energy-yielding compounds, on the one hand, and on the other divest themselves of the products which may represent waste of valuable secretions. There exists a general recognition of the fact that the passage of blood through these minute branches leading from the greater highways of transport varies greatly, the rate of flow being very inconstant. The explanation usually given is that, since the capillaries are assumed to be passive structures, these variations in flow within them are probably associated with alterations in the vasomotor conditions of the small arteries or arterioles supplying them. In other words, the rate of flow in the capillary circulation is determined, according to the most prevalent conception, by the state of contraction or dilatation of the corresponding arteriole. Dilatation of the latter will bring about a rise of pressure in the capillary which will correspondingly expand, ready to resume its original form whenever the relief from arterial pressure permits the inherent elasticity of the minute vessel to come into play again.

Certain facts are not easily reconciled with such an explanation. It has been observed many times that even within the same circumscribed tissue the blood may be flowing though some of its capillaries are empty. There are objections to the assumption that these different capillaries have unlike coefficients of elasticity so that they require different pressures to open them. An alternative and comparatively novel hypothesis endows the capillaries with the capacity of active contraction and dilatation. Long ago it was argued that the cell substance in these structures is arranged in strands running from the nuclei around the capillary. By contraction of these strands in some parts of the circulation the vessels were asserted to be narrowed to obliteration.

The original observations on capillary contraction were made by Stricker in 1865 on the maturing membrane of the frog. Krogh¹ of Copenhagen University has recently presented new evidence showing that the capillaries are not merely passively dilated by blood pressure but constantly perform active changes in caliber. In resting muscles most of the capillaries are in a state of contraction and closed to the passage of blood. In certain cases it was demonstrated that the

maximum amount of blood that can be present in the capillaries is not less than 750 times the minimum. The arterial blood supply is not thus variable. Consequently the blood color of a tissue depends practically on the state of contraction of the capillaries and not primarily on that of the arterioles. Krogh is quick to point out the consequent deduction that the capillariomotor regulation must play an enormous rôle not only in muscles, but in the skin and in all mucous membranes, in which changes in color are the most obvious signs of vasomotor influences. The hyperemic condition (in the clinical sense) of any organ is brought about by a large number of capillaries being open and more or less dilated; and in the anemic condition most of the capillaries are closed, and most of those which remain open are more or less contracted.

If a contractile power is widely present in the capillaries it can doubtless be affected profoundly by chemical substances produced as the result of metabolism, either normal or abnormal, in the surrounding tissues. Dale and Richards² have intimated a belief in a mechanism capable of regulating capillary tone and situated in the capillaries themselves. This factor has in fact been depended on to support some of the recent hypotheses concerning the genesis of shock.³ The entire conception of a caliber-regulating potency within the capillary wall, assigning to the minutest vessels powers formerly ascribed solely to the smaller arteries, is all but revolutionary in present-day physiology. Its obvious importance makes added confirmatory researches and the establishment of the nature and susceptibility of the contractile factors imperative.

FEVER AND THE WATER RESERVE: A PHYSICOCHEMICAL THEORY

In the course of the important studies by Woodyatt⁴ and his associates on intermediate carbohydrate metabolism, timed injections of glucose and other substances being given intravenously by means of ingenious motor-driven pumps, it was observed that under certain conditions fever would result. Fever came on when glucose was injected in such quantities that marked glycosuria and diuresis developed, provided that in the mean time, water was withheld until the body lost some weight. Under such conditions chills were noted also. Naturally the thought arose that under these conditions there might not be enough available water left in the body to cool it by evaporation, but of course the possibility that the sugar injections in some way disturbed a nervous heat-regulating center has to be considered.

1. Krogh, A.: The Supply of Oxygen to the Tissues and the Regulation of the Capillary Circulation, *J. Physiol.* **52**: 457 (May 20) 1919.

Pediatricians have previously discussed these and other possible explanations of so-called sugar, salt and thirst fever, without reaching any definite settlement. The results of the new experiments by Woodyatt and his associates, being made under the best controlled conditions so far attainable, make a significant contribution not only to the study of experimental fever but also to the theory of fever in general. It is remarkable to what heights the temperature of the body may be driven by the method used in these experiments: fever of 111 F. is produced readily, and in one case the temperature of a dog in the course of ninety minutes, rose to 125.6 F., the highest animal temperature on record, as the consequence of a timed intravenous injection of glucose solution during which the fluid output exceeded the intake by 616 c.c. (100.2 c.c. per kilogram). The results show further that increased combustion of glucose is not a necessary factor, and that fever can be produced in dogs that have been rendered poikilothermic by severance of the cervical cord; hence this fever is not dependent on a nervous heat-regulating center.

The outstanding fact in these experiments is that single injections of glucose (and certain other substances like salt and lactose) may produce fever when the body is depleted of water. The condition is similar to the inanition fever of the new-born described by McLane and Crandell, and to the salt and sugar fevers of infants, all of which are relieved by water. These fevers consequently may be looked on as "thirst fevers" due to reduction of the amount of water in the body available for evaporation at the normal temperature. The question arises: Is the fever of the ordinary febrile diseases of the same nature?

Balcar, Sansum and Woodyatt have discussed the possibility that the fever of typhoid and other febrile diseases may be the result of a lack of free water, available for evaporation, because the colloids of the body are changed by the poisons of the infection, so that they take up and bind more water than in health. They point out that this idea receives support from the concentration of the blood and secretions in infectious fevers, the cloudy swelling of the cells, the thirst, and the sudden release of large amounts of water in the urine and sweat when the fever ends by crisis, as in pneumonia. The liters of water given off during a few hours in such a crisis can be accounted for only on the score of water retention during the febrile stage. Whether we shall be able to measure the variations in the amount of free water in the blood that may occur in fevers remains to be determined, but it is not at all unreasonable to expect that a method that might be suitable for clinical use may be devised for this purpose. We know that plenty of water is beneficial in many febrile diseases, but "probably no one has yet daringly pushed the administration of water in fever to the ultimate limits which might be necessary to

ascertain whether every fever can be made to disappear entirely if enough water is given."

The results in this direction mentioned by Balcar, Sansum and Woodyatt are, of course, only tentative as yet, and the outcome of the work in progress will be awaited with much interest. For the present, emphasis is placed on the fact that a new, well formulated and well founded theory of fever is advanced, according to which fever may result from the lack in the body of water available for evaporation, and in infectious diseases such lack may be caused by an abnormal increase in the power of the proteins of the body to absorb and bind water. Undoubtedly this physicochemical theory of fever will prove of much value in stimulating experimental work, and it is possible that it may lead to important advances in the treatment of febrile diseases.

THE METABOLISM OF BILE ACIDS

The daily discharge of a pint of secretion containing more than half an ounce (15 gm.) of substances, of which several are chemically unique, into the alimentary tract is a phenomenon that ought to excite considerable interest and speculation. Abnormalities of the biliary functions, to which we obviously refer here, are a frequent problem for surgical consideration as well as a source of pathologic manifestations that every physician is called on to treat. Nevertheless, the physiology of the bile still continues to be enshrouded in no little mystery. The importance of the bile in certain of the digestive functions, particularly in relation to the utilization of fats, has come to be well realized. It is sometimes claimed of late that this secretion acts as a regulator of intestinal putrefaction, because of a slight laxative property whereby the intestinal contents are expelled before bacteria develop in them to any great extent; and perhaps this theory accounts for the occasional employment of bile preparations in therapy. Whether the bile, which has unusual properties as a solvent, on this account represents an excretory vehicle of special importance is also questionable.

There is almost as much uncertainty regarding the origin of the bile constituents as seems to exist with respect to their performance in the organism. Gradually new items of information are coming to light. Many years ago the Genevan physiologist Schiff¹ became sponsor for the belief that there is a "circulation of the bile," by which is meant a reabsorption of bile discharged into the intestine. With respect to the bile pigments, those long known, peculiar biochemical substances, Hooper and Whipple² of San Francisco have furnished definite proof that they are not absorbed from the intestine at least. Other recent

1. Schiff, M.: *Arch. f. d. ges. Physiol.*, **3**: 598, 1870.

2. Hooper, C. W., and Whipple, G. H.: *Am. J. Physiol.*, **43**: 264 (Jan.) 1917.

investigations conducted at the George Williams Hooper Foundation for Medical Research at the University of California have greatly enhanced our knowledge regarding the metabolism of the bile acids.³ In experiments on fistula dogs they have demonstrated anew the familiar chologogue action of bile, bile salts, and the biliary acids. When these are given by mouth, the increment of excretion is exhibited within the following four to six hours.

This chologogue effect is apparently not attributable primarily to the amino-acid component of the conjugated bile acids ingested; for taurin (derived from taurocholic acid) has no effect on the output. On the other hand, cholic acid by mouth usually causes a distinct chologogue effect. Cholic acid fed during long periods of fasting gives a minimal output of bile acids; but fed during full diet periods gives a maximal output of bile acids. This outcome probably depends on the available supply of taurin, which is much reduced after fasting, but is abundantly available during full diet periods. In other words, according to Foster, Hooper and Whipple,³ cholic acid is the limiting factor which determines the level of bile acid excretion in the bile. The sulphur-containing taurin is derived in all probability from the amino-acid cystin of the food or body protein. Taurin, like its analogue glycocholl, appears to be present in excess of the amount needed to combine with the cholic acid of normal metabolism. Somehow the literature relative to the bile has transmitted the conjecture that cholesterol and cholic acid are in some way genetically interrelated. However, since neither cholesterol fed alone or combined with taurin nor hemolyzed red blood cells caused a change in the excretion of bile acids, Foster, Hooper and Whipple give no credence to the traditional statement.

One cannot study the reports of the California laboratory without gaining the conviction expressed in them that both endogenous and exogenous factors are concerned in the metabolism of bile acids. Thus, in the dog which excretes this acid only, there is a reasonably constant output of taurocholic acid during fasting periods, and the output may be somewhat diminished by feeding carbohydrates. The relative diminution of urinary nitrogen and of bile acid excretion under these circumstances is quite in harmony with the well known protein-sparing effects of carbohydrates in metabolism. It is equally clear, to quote Whipple and his associates, that there is an important relationship between the output of taurocholic acid and the intake of certain food proteins. On certain

diets a uniform level of bile acid excretion may be observed for days; and a sudden shift to a similar diet, containing double the amount of food nitrogen, may cause a sudden doubling of bile acid excretion. Meat protein seems to be particularly efficacious.

It is now known that bile pigments can be formed outside of the liver and excreted in the bile secondarily. For the bile acids the evidence points to the liver cells as the essential seat of formation. At any rate, on a standard diet a functionally deficient liver produces far less than the normal amount of bile.

Current Comment

ANTHRAX

During the past eighteen months, attention has been especially directed to anthrax in this country by the considerable number of shaving brush cases reported from various army camps. But, for some years before the United States entered the war, anthrax had apparently been gaining in frequency and had been a cause of increasing concern to health officers in many places. In Massachusetts, twenty-five cases were reported in 1916 during a period of little over four months, and in Louisiana in the same year ten cases were reported in a single month. Other recent cases have occurred in Mississippi, Wisconsin, New Jersey, Connecticut and Kansas. In the whole United States there have been probably at least fifty deaths a year from anthrax since the beginning of 1915. As is well known, anthrax is primarily a disease of herbivorous animals and is communicated to man chiefly through contact with hides and other animal products. It is believed that the disturbance of the usual channels of import by the war, combined with the scarcity of labor, has led to a less efficient preliminary disinfection and so has permitted the introduction of anthrax-contaminated hides, bristles, etc., from parts of Asia and South America. The present increased scarcity of leather is likely to draw still further on out-of-the-way and uncontrolled sources. There are only about twenty establishments in the United States that manufacture shaving brushes, and the U. S. Public Health Service has found the widest range of practical efficiency in their methods of sterilizing the hair or bristles. Safety, however, can be very simply attained. Boiling or steaming the hair has been found a satisfactory means of treatment. The apparent increase of anthrax cases due to contaminated shaving brushes raises the question whether there has been a real increase in infection or whether the better opportunities for early diagnosis and bacterial examination are responsible for bringing to light a larger proportion of cases. It is to be hoped that, for some time to come, infections simulating anthrax whether in country or city will be scrutinized with this possibility in mind. The increase in anthrax that occurred before our own mobilization suggests that the infection may have been even more wide-spread than was recognized. At all events, the future development of this dangerous dis-

3. Foster, M. G., and Hooper, C. W.: The Metabolism of Bile Acids. I. A Quantitative Method for Analysis of Bile Acids. *J. Biol. Chem.*, 28: 355 (June) 1910. Foster, M. G.; Hooper, C. W., and Whipple, G. H.: II, Normal Fluctuations in Healthy Bile Fistula Dogs, *ibid.*, p. 367; III, Administration by Stomach of Bile, Bile Acids, Taurine, and Cholic Acid to Show the Influence on Bile Acid Elimination, *ibid.*, p. 379; IV, Endogenous and Exogenous Factors, *ibid.*, p. 293; V, Control of Bile Ingestion and Food Factors, *ibid.*, p. 413; VI, Origin of Taurocholic Acid, *ibid.*, p. 431.

case should be watched with care. The Public Health Service has found reason to state recently that "without doubt there are now in the market many brushes which are potentially dangerous."

EARLY AWARDS OF THE WAR RISK INSURANCE BUREAU

The Federal Board for Vocational Education has recently published an analysis of the awards of compensation for disability in the first 15,245 cases examined and adjusted by the War Risk Insurance Bureau. It represents approximately reports of awards to June 20, 1919, and will serve to give some advance indication of the types of specific disabilities most frequently demanding consideration. We have already pointed out that during the present war only 2 per cent. of the disabilities are attributed to loss of limbs, whereas in the industries 26,000 limbs, equivalent to six times the number of amputations among American soldiers in the year of war, are lost each year. Hence the justification for the pertinent query reiterated by government publications until it has almost become a postwar slogan: "As soon as we have made peace in Europe can't we do something to prevent the wounding of workmen at home?" Nearly one half (46.6 per cent.) of the cases with a specified class of disability in the War Risk Insurance Bureau report are comprised under the title "Disease," in contrast with amputations, ankylosis, injuries, impairment of sight or hearing, paralysis, etc. Tuberculosis has first place with a record of more than 3,000 out of a total of 7,103 disease cases. Heart affections take second rank in the frequency of their incidence. Arthritis, empyema, nephritis, pneumonia, pleurisy and rheumatism each represent about 2 per cent. of the "diseases" recorded. Next in the order of frequency were the injuries not involving amputations or ankylosis. Out of the 26 per cent. of disabilities in this class, the arms and legs were most frequently involved. Total blindness was not a prominent misfortune; it included only twelve out of 536 cases of impairment of vision. Two hundred and eighty-six persons were accepted as "gassed." Out of the entire number of claims, 74 per cent. were awarded a compensation of \$30 a month, most of the remainder receiving a slightly higher allowance.

THE CARRIER PROBLEM IN MENINGITIS

"With the advance of scientific research our old pet theories go on the scrap heap while new theories are evolved. Now that transmission of disease through the air and by fomites has been disproved, the present explanation is that communicable disease is transmitted only by means of infected persons, unrecognized cases and healthy carriers." This statement by Shaw,¹ which many will hesitate to accept in toto, forms the basis for an appeal for public health legislation in regard to the carrier problem. A questionnaire sent to the various state departments of health brought answers showing how unlike are the

methods pursued in different localities with respect to the carriers of meningitis organisms. As Shaw has demonstrated by the record of a so-called sporadic case of meningitis on an isolated farm in which a visiting soldier was found to be responsible for the infection, it is no longer sufficient merely to isolate the known cases—a procedure which constitutes the sole preventive measure in certain states. In this country the extremes of attitude are represented, on the one hand, by a state like Missouri, in which the state board of health has no statutory authority in the case of communicable diseases, and on the other hand, by New York. There contact carriers are excluded from public assemblies. If the patients with meningitis are not isolated, others in the household are quarantined. Carriers are made subject to special rules and regulations of the state department of health. Patients are isolated, if possible, until three successive cultures from the nasopharynx at intervals of not less than five days are free from meningococci. If we recall the assertion that there are ten carriers to every patient,² and that "carriers beget carriers," it must be manifest that some uniform legislation regarding the latter is highly essential if substantial prophylactic progress is to be made. No state can succeed, however careful its preventive measures against infection may be, so long as an indifferent neighbor neglects an obvious hygienic duty.

REPORT OF HEALTH INSURANCE COMMISSION OF THE STATE OF ILLINOIS

Elsewhere in this issue³ appears a summary of the report issued by the Health Insurance Commission of the State of Illinois. This statement of conclusions will afford a brief insight into some of the problems investigated by the commission. The report affords, moreover, a most valuable study of a number of medical sociological problems which should be read with interest by every physician who is interested in the social aspects of his profession. It includes, in addition to its investigation of the extent, cost, causes and results of sickness and death among wage earners and their families, sixteen special investigations. These concern a study of dispensaries and clinics in Illinois, occupational diseases, the health of coal miners, fraternal insurance, the present status of health work in the public schools, and an analysis of sickness insurance as it has developed to date in Germany, Great Britain and the United States. The material seems to have been carefully worked up, and the report contains such valuable data that it will be of decided help to sociological workers.

Group Medicine.—Certainly the time has come when, on the one hand, the coming together of physicians for organized practice should be permitted both by law and by public opinion. On the other hand, no such organization, whether called a hospital, a mutual medical organization, or any other group, should be permitted to carry on the diagnosis and treatment of disease except under some form of public supervision. —M. M. Davis, *Am. J. Pub. Health* 9:300, 1919.

Medical Mobilization and the War

Personnel of the Medical Department

For the week ending August 22, there were 8,166 officers in the Medical Corps, a decrease of 729 from the previous week. The Medical Reserve Corps contained 3,287. The total number of physicians discharged since the beginning of the war is 23,967.

Military Surgeons to Meet

The Association of Military Surgeons of the United States will hold its 1919 meeting in St. Louis, October 13 to 15, under the presidency of Henry P. Birmingham, Brig.-Gen., M. C., U. S. Army. Dr. Nathaniel Allison is chairman of the local committee of arrangements and has appointed the following chairmen of subcommittees: program, Dr. Eugene L. Opie; reception, Dr. Walter Fischel; entertainment, Dr. William H. Mook; finance, Dr. Hanau W. Loeb; ladies, Dr. Vilrag P. Blair, all of St. Louis. This is the first meeting of the association since the end of the world war and some questions of considerable importance are expected to be decided during the session.

Senate Passes Bill for Retiring Army Nurses

The United States Senate has passed a bill introduced by Senator Wadsworth of New York to authorize the retirement of the members of the United States Army Nurse Corps. The measure provides that members of the Army Nurse Corps who have twenty years' active service, including time served as contract nurses, are to be placed on a retired list and receive 75 per cent, exclusive of foreign pay, of the amount they were receiving on active service. The measure has been referred to the House of Representatives for action, and it is thought that the House will pass it. Members entitled to the benefits of this act must make application to the Secretary of War. The measure passed the Senate without a roll call.

New Division in Surgeon-General's Office

A division of coordination, organization and equipment has been created in the Office of the Surgeon-General, with Alexander N. Stark, Col., M. C., as chief, and Albert P. Clark, Col., M. C., and Arnold D. Tuttle, Col., M. C., as assistants. The object of this division is to study medical department organization, with a view to recommending improvements, to maintain liaison with the corresponding divisions of other bureaus, with a view to standardization, equipment, transportation and activities in general; to revise, produce and maintain up to date all medical department service manuals; prepare organization charts and graphics of medical department activities for peace and war; to prepare and maintain tables of organization affecting the medical department; study the provisions of all general orders, circulars, etc., involving medical department policy prior to publication, and to perform such other functions as from time to time may be designated by the Surgeon-General.

Pictorial History of Medical Service

A pictorial history of the activities of the Medical Department of the Army during operations overseas, comprising about 75,000 feet of motion pictures, and 10,000 still pictures, has been turned over to the Surgeon-General's Office. Two prints of each picture made were filed and cross-filed according to organization, number and region. Fifteen pictures were taken of each hospital, showing personnel and aerial view of the buildings, views of the operating rooms and wards, sanitary features, views of patients and views of men under operation (the latter designed for instruction purposes), views of medical officers and men and surgical operations. Some of the pictures taken at the front show field hospitals and evacuation hospitals receiving and removing patients, medical supply depots, medical officers and men working in the field, and equipment they carried, showing contrast between what the personnel are taught in training camps in this country and how they actually work on a battlefield. The pictures show regimental surgeons going to the aid of men stricken on the field.

HONORABLE DISCHARGES, MEDICAL CORPS, U. S. ARMY

NOTE.—In the following list, L. signifies Lieutenant; C., captain; M., major; L. C., lieutenant-colonel; Col., colonel.

Medical News

(PHYSICIANS WILL CONFERR A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATIVE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

ARKANSAS

Held as Narcotic Law Violator.—Dr. S. F. Walker, Texarkana, is said to have been arrested on a federal warrant charging violation of the narcotic law, and after a hearing before the United States commissioner is said to have been held for the grand jury in bonds of \$2,000.

Medical Board Reorganized.—At the annual meeting of the state medical board for reorganization, at Little Rock, Dr. Julius A. Bogart, Forrest City, was elected president, and Dr. Thomas J. Stout, Brinkley, and Edward F. Eitz, Fayetteville, were re-elected secretary and treasurer, respectively.—Dr. William H. Toland, Nashville, has been appointed a member of the state medical board, succeeding Dr. Francis J. Isbell, Horatio.

Personal.—Dr. Lemuel E. Willis, Newport, is reported to be seriously ill at his home.—Dr. Henry H. Atkinson, Fordyce, has succeeded Dr. Claiborne J. March, Fordyce, resigned, as health officer of Dallas County.—Dr. Charles S. Holt, Fort Smith, has been appointed division surgeon of the Missouri Pacific system with headquarters at Fort Smith.—Dr. R. P. Boggan, Forrest City, has been reappointed health officer of St. Francis County.

ILLINOIS

New Hospital.—A new maternity hospital is to be built in Chicago, at Forty-Seventh and Mozart Streets, by Archbishop Mundelein. It will be known as Misericordia Maternity Hospital and will house 100 mothers and 150 infants. The initial expense of the institution will exceed \$100,000.

Base Hospital Officers Organize.—August 19, twenty-six officers of Northwestern University Base Hospital No. 12, held a meeting in Chicago to form a peace-time organization to hold together the personnel of the unit which achieved such notable success in France. Payson L. Nussbaum, Major, M. C. U. S. Army, was elected president; Kellogg Speed, Lieut.-Col., M. C. U. S. Army, vice president, and Stanley W. Clark, Capt., M. C. U. S. Army, secretary-treasurer, all of Chicago.

Paris-Chicago Hospital Foundation.—The Paris-Chicago Hospital Foundation has been incorporated in Illinois with offices in the Marquette Building, Chicago. The officers and directors of the association are: president, Dr. Charles H. Johnson; vice presidents, Dr. Truman W. Brophy and Mrs. E. C. Thomas; secretary, Mrs. Milan H. Hubert, and treasurer, Mrs. Archibald Freer, and the medical members of the board of directors are: Drs. Edmund J. Doering, William H. Wilder, Thomas J. Watkins and Lewis L. McArthur.

Personal.—Dr. Alice Barlow Brown, Waukegan, has returned after twenty-two months' service in France. Dr. Dr. Antony Blankin, Chicago, one of the founders of the Anglo-Slav National League of America and president of the league for several years, has been decorated by the Yugo-Slav government with the Order of St. Sava.—Dr. John A. Kappelman, Chicago, has been appointed full-time health officer of

Canton with a yearly salary of \$3,300.—George G. Davis, Lieut.-Col., M. C., U. S. Army, Chicago, arrived in New York from France on the *Northern Pacific*, August 12.—Dr. Gertrude Moulton, Urbana, has been appointed assistant health officer and advisory physician for women students at the University of Illinois, Urbana.

IOWA

Physician Held to Grand Jury.—Dr. John W. Conaway, Hartley, charged with performing a criminal operation, which resulted in the death of a woman in Spencer, July 27, was held to the O'Brien County grand jury at bonds fixed at \$5,000.

Personal.—Dr. Louis Baumann, formerly director of research and assistant professor of medicine in the State University of Iowa, Iowa City, has been appointed associate in medicine at Columbia University and assistant visiting physician at the Presbyterian Hospital, New York City.—Dr. Henry Schmuckler, Waleton, sustained a serious stab wound of the leg in a quarrel, August 19.—Dr. William J. McDonald, recently Major, M. C., U. S. Army, sanitary inspector of the Thirty-Fifth Division, has been placed in charge of the students' health service at the state university, Iowa City.—Dr. Herman Fischer, Burlington, chief medical examiner of the Burlington system, with headquarters at West Burlington, has resigned to resume private practice, and has been succeeded by Dr. A. D. George, formerly examiner for the company at Lincoln, Neb.—Dr. John C. Newton, Exira, is reported to be seriously ill.—Dr. George F. Severs, Centerville, has been elected president of the state board of health, succeeding Dr. Walter L. Biering, Des Moines.—Dr. Jeannette F. Throckmorton, Chariton, has begun work in Des Moines under the supervision of Dr. Willard E. Corlank, recently appointed director for venereal disease work in Iowa.—Dr. Charles F. Noe, Amama, and Dr. Gershon H. Hill, Des Moines, have been elected members of the board of curators of the state historical society.

KENTUCKY

New Hospital.—Drs. Amerida M. Gross and Robert L. Collins have purchased a residence at Hazard and are remodeling it for use as a hospital.

Chiropractors Arrested.—The state board of health, June 30, arrested six chiropractors and naturopaths on charges of practicing medicine without a license. The six are: C. B. Sutherland, J. T. Finch, W. T. Aushbrook, W. H. Dunn, A. Loscy and H. C. Pirfile.

Clinic Holding Company Incorporates.—The Clinic Holding Company, Lexington, filed articles of incorporation with the Fayette County clerk, August 12. The corporation has an capitalization of \$100,000 and is empowered to hold real estate and personal property for the purposes of holding clinics, and to carry on a general practice. The incorporators are Drs. David Barrow, Waller O. Bullock, Ernest R. Bradley, Julian T. McClymonds, Charles C. Carr, Frank H. Clarke, William T. Briggs, Walter S. Wyatt and D. Woolfolk Barrow, all of Lexington.

LOUISIANA

Camp Hygeia Title Transferred.—The Orleans Anti-Tuberculous League has acquired the title to Camp Hygeia in St. Tammany Parish, and the charter for the league has been issued.

Hospital Completed. Emory Hospital, New Orleans, has been completed by the Southern Pacific Railway for the first-aid treatment of its employees. It is located at Atlantic Avenue and Evelyn Street.

Appeal for Funds for Lepers. A committee has recently been formed in New Orleans to secure \$5,000 for an amusement fund for 150 men and women who are inmates of the Louisiana Lepers' Home, Carville.

MARYLAND

Plans to Combat Influenza. The Baltimore City Health Department is making preparations and taking every precaution to combat an influenza epidemic, should there be a recrudescence of the malady this fall.

Drug Clinic Opened. A clinic for drug addicts of Baltimore has been put into operation at the headquarters of the Volunteers of America by Captain Loga, in cooperation with the city health department and the internal revenue bureau. More than 300 patients can be cared for by the clinic, which

already has three physicians in attendance, with the expectation of a fourth. It is estimated that there are not 300 genuine addicts of the habit in Baltimore, at least not that many who are too far gripped by the habit to take care of themselves.

MASSACHUSETTS

Semicentennial of State Health Department.—The Massachusetts State Health Department will celebrate its semicentennial at the State House, Boston, September 15, under the auspices of the Massachusetts Medical Society, and the associated boards of health and the state health department.

Third School for Feeble-minded Provided.—The legislature of 1919 appropriated \$250,000 for the Belchertown School for Feeble-minded. The present farm colony is being enlarged and a railroad spur is being laid to the plant. The appropriation will provide for the erection of a store house, bakery, laundry, power house and custodial building for 140 inmates, a dormitory for 105 and the necessary building and road constructions.

Administrative Functions Reorganized.—In accordance with the provision of the revised state constitution the functions of the department of public health are set forth as follows: "The Department of Public Health shall consist of the State Department of Health and include a division of sanitation, with the power of the board of trustees of the hospitals for consumptives, which is abolished. Penitentiary hospital shall also be in this division."—The department of mental diseases includes the commission on mental diseases and the control and supervision of the Norfolk State Hospital.

Personal.—Frederick T. Clark, Westfield, Capt., M. C., U. S. Army, chief of the ophthalmic service at U. S. Army General Hospital No. 1, New York City, has been promoted to the rank of major, M. C., and been made chief of the combined ophthalmic and otolaryngologic service in that hospital.—The increase in the salaries of medical examiners (coroners) Leary and McGrath, Boston, from \$4,000 a year to \$5,000 a year was approved by Mayor Peters, August 5.—The active work of Dr. Dudley A. Sargent, Cambridge, as director of the gymnasium at Harvard, has closed with the completion of forty years of service in that capacity. No successor has as yet been appointed.—Dr. S. Burt Wolbach, Boston, has returned from Mexico where he spent more than a month in study and research work as to the cause of typhus fever.—Dr. Loring B. Packard has resigned as superintendent of the Brockton Hospital on account of ill health.

MISSOURI

Advisory Board Appointed.—Dr. Thomas B. M. Craig, superintendent of State Hospital No. 3, Nevada, has selected a number of physicians throughout the state to act as an advisory board of the hospital and the plans have received the approval of the board of managers. This is believed to be the first time the superintendent of a state hospital has created a board for the purpose of cooperating with the superintendent in an advisory capacity.

Society Establishes Clinical Section.—About 100 members of the St. Louis Medical Society have established a clinical section of the society and have organized the clinical material available for graduate instruction. There will be clinics in general surgery and medicine as well as in the various special branches so that visiting physicians will have an opportunity to obtain graduate instruction not hitherto open to them in St. Louis. It is announced that these clinics will be ready, October 1.

Personal. Dr. Emmett S. Ballard, St. Joseph, has been elected a member of the school board to succeed Mr. S. I. Motter, resigned, and Dr. Hasbroeck DeLamater has been reelected director of hygiene in the schools of St. Joseph.—Dr. Borden S. Veeder, St. Louis, has received from Great Britain the decoration of Companion of the Order of St. Michael and St. George.—Dr. Dudley S. Conley has been appointed to succeed Dr. Max Meyer in the medical faculty of the State University, medical department, Kansas City.

NEW YORK

Red Cross Workers Honored by Serbia.—According to a recent report from Belgrade, Red Cross workers from nine cities in New York have been decorated by Prince Alexander of Serbia. Among this number are Major F. L. Emerson of New York and Dr. Regina F. Keyes of Buffalo who received the Order of the White Eagle. Dr. Francis M. Flood of Elmira received the Order of St. Sava.

New York City

Deaths from Wood Alcohol.—Within two days three deaths from wood alcohol were reported from a locality in the Bronx. Following these fatalities Nathan Allowitz and his wife were arrested and held in \$20,000 bail for selling wood alcohol. They were found to be in possession of 13 gallons of a liquid which the health department stated was wood alcohol.

Personal.—Dr. S. Josephine Baker, director of the bureau of child hygiene, was recently appointed a member of the advisory committee for the Federal Children's Bureau at Washington, and as such has been designated special agent of the children's bureau in New York City.—Dr. Lucius P. Brown, director of the bureau of food and drugs of the department of health, has been honorably discharged from the service and has resumed his duties with the health department.

New Health Department Building.—Health Commissioner Royal S. Copeland announced, August 19, the tentative approval of a plan for a twelve-story, health headquarters' building on Thirtieth Street, between Sixth and Seventh avenues, to cost \$1,000,000. The building will occupy a site already belonging to the city. Three or four floors will be given up to laboratories. There will be an auditorium, clinic rooms, model health stations, room for vaccinations, records, etc.

Jacobi Memorial Plans Expanded.—Some time ago it was announced that in the fall a campaign would be carried on to raise funds for a hospital in the Washington Heights section of New York as a memorial to Dr. Abraham Jacobi. These plans have been developed in a somewhat different way and it is now announced that appeals will be sent to 140,000 physicians in the United States for contributions to a \$1,000,000 fund, a large part of which will be devoted to the endowment of the institution after it is built. It is now stated that the memorial will be for children only and will probably be erected as an annex to the Jewish Memorial Hospital. The institution will be non-sectarian in character and an endeavor will be made to enfold as many free beds in the hospital as possible as a tribute to Dr. Jacobi's labors among the poor of the city.

NORTH CAROLINA

Library for Medical Society.—A medical library to contain the latest medical works and periodicals is planned by the Mecklenburg County Medical Society, the members of which have already subscribed \$1,000 toward building up the present medical society library at Charlotte.

Veneral Disease Clinics Established.—The eighth clinic for the treatment of venereal disease in North Carolina has been established at Clinton, and is under the charge of Dr. Eddie T. Collingsworth. Other clinics are now in operation at Charlotte, Rocky Mount, Wilmington, Fayetteville, Asheville and Winston-Salem, and it is expected a clinic will be opened at Greensboro in a short time.

Hospital Notes.—At the meeting of the Gaston County Medical Society, August 6, efforts looking toward the erection of a municipally owned hospital for Gastonia, Gaston County, were unanimously endorsed.—Laurel Hospital at White Rock, Madison County, was recently completed and will be under the charge of Dr. George H. Packard. Drs. Kinchin C. Moore, Henry B. Best, Ernest S. Strickland and P. L. Lane are interested in the organization of a hospital for Wilson with a forty-bed capacity and to cost \$50,000.—Work has been started on an addition to the Appalachian Hall Sanatorium, Asheville, to cost \$15,000.

Personal.—Dr. Willbur A. McPhaul, Lumberton, who has been health officer of Robeson County for two years, has resigned to accept the position of director of rural sanitation of the state of Alabama.—Drs. Frederick M. Hanes and Thomas W. Davis, Winston-Salem, have been elected members of the Winston-Salem City Hospital Commission.—Drs. Richard H. Lewis, Raleigh, and E. J. Tucker, Roxboro, have been appointed members of the state board of health to fill vacancies.—Dr. C. Curtis Hudson, city health officer of Charlotte, has been appointed chairman of the section of public health of the Medical Society of the State of North Carolina.

OHIO

Personal.—Dr. Clifton F. McClintic, assistant dean of the medical department of the University of Cincinnati, has resigned. His resignation will take effect, September 1. He has accepted a position in the Detroit College of Medicine

and Surgery.—Dr. Jonathan Forman, Austintown, has resigned as assistant professor of pathology in the Ohio State University.—Dr. George Huntley, Oberlin, for thirty years a medical missionary of Shanghai, China, has returned on leave of absence of a year.

Trachoma Campaign.—The state department of health has opened a campaign to rid Ohio of trachoma which is especially prevalent in the counties bordering on the Ohio River, where the disease is believed to have been spread from the mountain districts of Kentucky and West Virginia. An intensive campaign is to begin at once in Scioto County. The state authorities will be aided by trachoma experts from the United States Public Health Service. Every schoolchild in the county will be examined as soon as school opens and free clinics for persons unable to pay for the necessary medical treatment will be established in September.

Training Course for Hospital Executives.—A division of hospital administration will be added to the department of industrial medicine and public health of the Medical College of the University of Cincinnati. Instruction will begin with the opening of the fall semester of the medical college, and will consist of twelve months of didactic and practical training. The work will be so arranged as to provide for practical instruction in the various cooperating hospitals of the Cincinnati district during the morning hours. The afternoon hours will be devoted to didactic lectures, round table conferences, quizzes, discussions and survey trips in groups. The courses of instruction will not be confined to physicians, but will be available to all persons whose individual qualifications are approved by the director, and whose preliminary education will permit them to matriculate in the university. Certificates will be awarded to students satisfactorily completing the prescribed courses, which will indicate the nature and extent of the work pursued.

OKLAHOMA

Health Conference.—The second annual Oklahoma State Public Health Conference will be held in Oklahoma City, September 23 and 24, under the auspices of the Oklahoma Tuberculosis Association and the state department of health.

State Board Elections.—At the meeting for organization of the state board of medical examiners, July 10, H. C. Montague, Muskogee, was elected president; Dr. Lewis E. Emanuel, Chickasha, vice president; Dr. James M. Byrum, Shawnee, secretary, and Daniel W. Miller, Blackwell, treasurer.

Field Secretary Employed.—The Oklahoma Tuberculosis Association has employed a medical field secretary, whose duty will be to tour the state, advise other physicians on modern methods of diagnosis and treatment of tuberculosis and also to conduct clinics in various cities of the state.

PENNSYLVANIA

Enlarge Insane Hospital.—The board of trustees of the Homeopathic Hospital for the Insane at Kittersville awarded contracts for the construction of four new buildings, including a home for women nurses, a nurses' dining room, sleeping quarters for employees and a double farm house. The total cost will be more than \$75,000.

Personal.—Dr. James R. Montgomery, Bloomsburg, has been appointed county medical officer by the state department of health, succeeding Dr. Samuel B. Arment.—Dr. William L. Estes has been appointed chief of the Genito-Urinary Dispensary of South Bethlehem by Commissioner of Health Edward Martin.—Dr. Lloyd McCarthy, Altoona, announces his retirement from practice.

Conference of Industrial Physicians.—The ninth conference of Industrial Physicians and Surgeons of the State Department of Labor and Industry will be held at the State Capitol, Harrisburg, September 22, in cooperation with the annual session of the Medical Society of the State of Pennsylvania. The program includes a symposium on health insurance, and papers dealing with the workmen's compensation act, and the sanitary disposal of sewage and trade wastes.

Philadelphia

Personal.—Dr. Samuel T. Orton of the University of Pennsylvania Hospital has been secured as head of the new psychopathic hospital at Iowa City, which is being erected at a cost of \$150,000.—Dr. Matthew F. Czupak has been elected surgeon-general of the Foreign War Veterans.—Dr. Arthur Dare, Lieut.-Col., M. C., U. S. Army, has returned home after several months' service abroad.

Hospital Seeks Fund.—A drive to obtain \$50,000 for the Frederick Douglass Memorial Hospital began, August 20. So far, more than \$800 has been collected. The bill awarding the annual state appropriation of \$22,000 to the institution provided that if the board of managers of the hospital refused to dismiss Dr. Nathan F. Mossell, as head of the hospital, the appropriation should not be granted.

SOUTH CAROLINA

Personal.—Frank D. Mower, Major, M. C. S. C. N. G., Newberry, has been appointed a member of the staff of Governor Cooper, with the rank of lieutenant-colonel.—Dr. James A. Hayne, Columbia, state health officer, who has been ill in a hospital in Washington for several weeks, returned to his home, July 7, convalescent.

Hospital News.—A commission was issued, July 25, to the Edgefield Hospital which has a capital stock of \$50,000. The incorporators are Drs. Albert R. Nicholson, Robert A. Marsh, Edgefield, and John N. Crafton, Colliers.—Excavation was commenced, July 21, for the new Spartanburg Hospital on North Church Street. The building will be four stories with basement in height, fireproof, and will cost about \$200,000. The new hospital will absorb the Good Samaritan Hospital and Spartanburg Hospital, and it is expected the building will be ready for occupancy Jan. 1, 1920.—A hospital building is being erected at Chesnee, by Dr. Joseph B. Cash, at a cost of about \$30,000. The hospital will have six wards and twenty-seven rooms, and it is expected that it will be ready to receive patients by November 1.—The annex of the Piedmont City Hospital will be ready for occupancy about the middle of September.—The campaign for the first unit of the Palmetto Sanitarium for Negroes, Columbia, was terminated, July 10, when a sum of \$6,000 raised by negroes of the state was presented to the state board of health. A sum of \$10,000 was provided by the last legislature for the purpose of providing a sanatorium for negroes of the state.—The Steedly Clinic and Sanitarium, at Chick Springs, was formally opened, July 10. The institution is under the care of Dr. Benjamin B. Steedly, Spartanburg.

SOUTH DAKOTA

Work on Asylum Site Begun.—Work on the improvement of the site for the Northern Hospital for the Insane, located just south of Watertown, has been commenced.

New Hospital.—The state board of charities and corrections has purchased 153 acres of land between the State Hospital and the city of Yankton, for the use of the hospital.—It has been decided to erect a hospital in Beresford to cost between \$60,000 and \$65,000.—Work has been started on a new hospital building at Sisseton, which will be under the charge of Dr. John W. Powell, and will provide quarters for fifteen patients.—Articles have been filed by Dr. Robert S. Westaby, J. A. Johnson and R. W. Rooney for a new hospital at Madison with a capital of \$100,000.

WASHINGTON

Personal.—William I. McClure, Lieut.-Col., M. C. U. S. Army, North Yakima, has returned after two and a quarter years' service abroad.

Tuberculosis Clinic to Open.—It is announced that the Spokane County Tuberculosis Clinic will be opened by September 1, with headquarters in Spokane.

State Society Meeting.—The Washington State Medical Association will hold its annual meeting in Spokane, September 11 to 13, under the presidency of Dr. Herman P. Marshall, Spokane.

Smallpox. For the first six months in 1919, smallpox headed the list of communicable diseases in Washington, with 2,138 cases; mumps followed with 2,070; chickenpox, with 1,357; scarlet fever, with 1,464, and measles, with 1,396.

Building for Medical Men. The Medical Building Company was recently incorporated at Seattle, with the following officers: president, Edward B. Frick; vice president, Dr. Philip V. von Pfandl; secretary-treasurer, William E. Robinson; and trustees, J. W. Sharpless and Dr. Homer D. Dudley, Seattle. The object of the organization is to build a modern office building for the exclusive use of physicians and dentists.

Medical and Safety Board Meeting.—The oath of office was administered, July 8, at Olympia, to members of the state medical and safety board. The state medical board is composed of Drs. John W. Mowell, Olympia, and J. S.

Klocher, and Mr. Martin Flyzik, and the advisory members are State Labor Commissioner C. H. Younger, and State Mine Inspector Bagley. The board has appointed Mr. John W. Pace as secretary and statistician.

GENERAL

Army Dental Surgeons Meet.—At the annual meeting of the Association of Military Dental Surgeons, Dr. E. P. R. Ryan was elected president; Dr. J. L. Brown, vice president; Dr. R. W. Waddell, secretary-treasurer, and Dr. William C. Fisher, editor.

Public Health Service Issues Pamphlet on Cancer.—The United States Public Health Service has just issued bulletins entitled "Cancer Facts which Every Adult Should Know." It is a 32-page pocket size pamphlet, giving the main facts regarding the prevalence of the disease and chief danger signals.

Meeting of Medical Veterans.—The trustees of the Medical Veterans of the World War will have a meeting in St. Louis at the same time of the meeting of the Association of Military Surgeons. The trustees of the veterans are: Col. Francis A. Winter, M. C. U. S. Army; Drs. Hubert Work, Pueblo, Colo.; Joel E. Goldthwait, Boston; George E. Brewer, New York City; John M. Dodson, Chicago, and Holman Taylor, Fort Worth, Texas.

Weeds and Hay-Fever.—As an endorsement of the efforts being made by the American Hay-Fever Association toward the reduction of the amount of pollen in the air, and the prevention or relief of suffering of many persons subject to hay-fever, the mayor of New Orleans issued a proclamation, August 17, urging all citizens to assist in the weed-cutting campaign, and asking the especial cooperation of the department of public property and the city board of health to the attainment of this end.

Occupational Therapy Society Meeting.—The National Society for the Promotion of Occupational Therapy will hold its third annual meeting in Chicago, September 8-11, at Bowen Hall at Polk and Halsted streets, under the presidency of Dr. William Rush Duncan, Jr. The general headquarters of the society during the conference will be at the Henry B. Favill School of Occupations, 825 West Polk Street. The annual banquet will be held, September 9, at the Hotel LaSalle, and September 11 will be spent in Milwaukee visiting hospitals in which occupational therapy is being employed.

Legislation for Study of Mentally Defective.—The study of feeble-minded, backward and otherwise mentally handicapped schoolchildren by the Bureau of Education is provided for in a bill introduced by Congressman L. C. Dyer of Missouri. (H. R. 8479.) The measure provides for the establishment of a new bureau in the Bureau of Education to collect information regarding feeble-minded children and for a mental laboratory to determine standards. A psycho-educational clinic is also provided. The sum of \$30,000 annually for the maintenance of this bureau is appropriated. A director is to be appointed at a salary of \$4,500.

Bequests and Donations.—The following bequests and donations have recently been announced:

Reading, Pa., Hospital, \$12,500, on the death of his son, Leonard, by the will of J. C. Ulig.

Tuxedo Hospital, Tuxedo Park, N. Y., \$100,000, by the will of Augustus D. Telford.

Methodist Hospital, Charlotte, N. C., a conditional bequest of \$15,000, by the will of B. D. Heath.

For endowment of hospital bed in memory of Dr. Stephen Seymour, Chicago, \$100,000, by the will of his daughter, Mrs. Catherine E. Brown.

Johns Hopkins University, Baltimore, \$20,000, by the will of Mrs. Hannah J. R. Creswell, Elton, Md.

National Exposition of Chemical Industries.—No profession in the United States has benefited more greatly by the war than that of chemistry; the tentacles of foreign monopoly in this field are cast aside, and America, with her vast resources, especially in minerals and coal tar, trusts in the ingenuity of her own chemists. In the past two years the strides of our chemical accomplishments have come up to expectations; it is simply necessary now to reveal what will be the probable progress of a promising future. In this connection the forthcoming "National Exposition of Chemical Industries" at the Coliseum and First Regiment Armory in Chicago, September 22 to 27, will be of great interest to all scientists—indeed it promises to be the epitomized exhibit of the new flourishing advances in chemistry. The fields of organic chemistry pertaining to dyes, pharmaceuticals, and various organic technical products are being

developed in America in a most commendable manner; in fact, the best achievement of the organic chemist during the war was along these lines and not the explorations in the realm of poisonous gases. To the physician, the exposition may thus be well worthy of investigation. Also, the United States Bureau of Mines will feature the protection of the employee from disease, accident or hazard arising from the development of this new industry. Meeting in connection with the exposition are a number of technical societies, thus assuring a comprehensive program.

Report of Illinois Health Insurance Commission.—The Illinois Health Insurance Commission, appointed by legislative act in 1917, has just issued its report in a book of 647 pages. The report includes a general investigation as to the extent, cost, causes and results of sickness and death among wage earners and their families, and a number of reports of special investigations. After a brief report of the general findings of the committee, a majority and minority report are submitted. The majority report, signed by William Beye, chairman, William Butterworth, Dr. E. B. Cooley, Edna L. Foley, Mary McEnerney and M. J. Wright, first states the general amount of sickness existing according to the survey. It is estimated that probably 20 per cent. of all wage earners will be disabled for more than seven days in the course of a year by a sickness or non-industrial accident, with an average of between twenty-seven and twenty-nine days for each wage earner disabled. It is estimated also that the cost of disabling sickness of wage earners alone in Illinois is about \$57,000,000 annually; and, if to this is added the medical bills paid for dependents, the cost of sickness in wage earning families is between \$80,000,000 and \$88,000,000 per year. It was found that sickness was the cause, or an accompanying condition of the dependency in from one third to one half the cases in which charity was asked. Tuberculosis and other chronic conditions are found in from 20 to 25 per cent. of the cases in which sickness is a cause or condition of dependency. In an analysis of the vital statistics of the state, an unfavorable showing is made by the data available for Chicago, relating to deaths of children under 2 years of age, from enteritis and diarrhea. These figures have increased in Chicago while in New York, St. Louis, Boston and some other cities, they have decreased.

The majority report also analyzes existing legislation for public health, the tuberculosis problem, venereal problem, maternity care and infant welfare work, hospital facilities and public health nursing. In its consideration of health insurance, it concludes that "it is apparent that a compulsory Health Insurance system comes in contact with so many interests of the individuals or groups who constitute society and affects them so vitally that the question must be solved in the light of a public demand or necessity and the welfare of the people of the state as a whole." Analyzing results in those countries which already have such systems, the committee finds that "it seems clear that compulsory Health Insurance is not an important factor in the prevention of diseases or in the conservation of health." The majority report concludes, finally, that it is the opinion of the commission that its findings do not justify it in recommending compulsory health insurance.

The minority report, signed by Dr. Alice Hamilton and Mr. John E. Ransom, states that the investigations made for the commission are "conclusive evidence of the need for a system of compulsory health insurance which would be applicable to practically all members of the wage earning group and would more equitably distribute the burden of the costs of sickness and would make more adequate provision for the medical care of wage earners and their dependents who become sick."

FOREIGN

International Physiology Congress.—Preparations are said to be well under way for a gathering at Paris in July, 1920, of scientists especially interested in physiology. The meeting is being organized by representatives from Great Britain, France and America, and invitations are to be sent to the neutral nations.

French Urologic Congress.—The Nineteenth Congress of the Association française d'urologie is to convene at Paris, Oct. 8, 1919. The only subject yet announced for discussion is the treatment of nontuberculous pyelonephritis in man. The opening address on this topic is to be by Dr. Ertzschoff of Paris. The secretary of the congress is Dr. O. Pasteau, avenue de Villars 13, Paris.

French Surgical Congress.—The Twenty-Eighth Congress of the Association française de Chirurgie is to convene at Paris, Oct. 6, 1919, Dr. C. Walther presiding. The three

subjects appointed for discussion are: simple traumatic lesions of the wrist; tumors in the vicinity of the kidneys; and cancer of the tongue. The secretary-general is M. J. L. Faure, 10 rue de Seine, Paris.

Volunteer to Fight Typhus.—Ninety men from the First and Third Divisions, all soldiers who speak Polish, have volunteered to work in Poland against the typhus epidemic, and have left the Coblenz area, on the first stage of the journey to Warsaw. The unit from the American Expeditionary Forces will number 550, and will be under the command of Col. Harry L. Gilchrist and Lieut.-Col. Lee R. Dunbar, Medical Corps. There will be required to transport the equipment and chemicals of the expedition, 800 railway cars and 700 motor trucks.

Institute for Sexual Science Founded at Berlin.—The *Nederlandsch Tijdschrift voor Geneeskunde* relates that the *Deutsche medizinische Wochenschrift* describes the opening, July 1, of an institute for *Sexualwissenschaft*. It says, "It is housed in a special building in the Thiergarten at Berlin, and is in charge of Dr. Max Hirschfeld. There are departments for sexual biology, sociology, ethnology and medicine. It is equipped for psychotherapy, electrotherapy, organotherapy and radiotherapy, and has a laboratory for microscopic and chemical research."

Deaths in the Profession Abroad.—Dr. A. Gouget, recently appointed to the chair of general pathology and therapeutics at the Paris medical faculty after long service as *agrégé*, aged 51. He was co-director of the *Presse médicale* and had published numerous works on the influence on the kidneys of disease in the liver, on insufficiency of the liver, etc. During the war he was at the head of the military hospital at Ton. —Dr. J. Gómez Ocaña, professor of physiology at the University of Madrid, author and an international authority on physiology, life senator, president of the recent First National Medical Congress in Spain, aged 59. —Dr. A. Demoulin of Paris, instructor in surgery and well known by his *expériences chirurgicales*, aged 59. —Dr. A. Raventos Aviño, a prominent surgeon of Madrid. —Dr. P. Reynier, professeur agrégé of the Paris medical faculty, surgeon to the hospitals.

Association of Radiologists of the Northland.—The *Ugeskrift for Læger* mentions that the Norwegian radiologist, Dr. Heyerdahl, invited the radiologists of the Scandinavian countries to meet at Christiana in July, on the occasion of the Surgical Congress. At the meeting it was decided to found the Nordisk Forening for medicinsk Radiologie, and the first representative meeting is to be held at Copenhagen in 1921. A number of communications were presented, on deformity of the eyeball with duodenal ulcer; on radium treatment of vulvar cancer, and on gallstones from the radiologic standpoint. Our exchange adds that Sweden has gone to the front in radiology under Professor Forsell's leadership. The board of the new association is to comprise two members from each of the countries of the Northland, besides the president, Prof. J. F. Fischer. The appendix and exophthalmic goiter are the topics for next year's meeting.

LATIN AMERICA

New Leprosarium in Brazil.—There has been begun in Brazil the construction of a model leprosarium near Santo Angelo, which will be the best of its kind in all South America and have all facilities for the isolation and treatment of lepers.

Prize to Guglielmelli and Delbon.—The *Semana Médica* of Buenos Aires mentions that the Felix de Azara prize for the two years 1915 and 1916 has been awarded recently to Dr. L. Guglielmelli and Dra. A. Delbon for their work entitled "Study of Textile Fibers of Animal and Vegetable Origin."

Death of Dr. Triani.—The death of Dr. Juan Triani is reported from Uruguay. He was 86 years old, was in his youth a medical officer of the Italian Army and had been fifty years in Uruguay. He was one of the founders of the School of Medicine of Montevideo and professor of legal medicine there.

Brazilian Psychiatry Journal.—The foundation is announced of the *Archivos Brasileiros de Neuropsiquiatria e Psiquiatria*, the first number of which has already appeared. There are four directors, all professors in these specialties, including Anstregesilo and Vianna, and the editorial staff consists of four other specialists.

Child Welfare Work at Lima.—The *Reforma Médica* of Lima, Peru, describes the foundation and the purposes of the Sociedad Protectora de la Infancia recently organized

there under the initiative of the alcade of the city. It aims to include also in its scope proper housing of wage earners and prophylaxis of transmissible diseases.

Institute of Physiology at Rio de Janeiro.—The Instituto Oswaldo Cruz has recently organized a section for physiology, with its special institute which has been placed in charge of Dr. M. Ozorio de Almeida. The only two other institutes in South America for teaching and research in physiology exclusively are at Montevideo and Córdoba.

New Preparatory School in Argentina.—A new preparatory medical school has been inaugurated at the University of La Plata where students will be able to study the first three years of the medical course. There is room for 200 students and the school will follow the plan of studies in force in the University of Buenos Aires. Dr. Pedro Belon is the dean.

Fiftieth Professional Anniversary of Rio de Janeiro Physician.—The Rio de Janeiro Medical Faculty and the board of the Museu Nacional joined together to do honor recently to the "golden jubilee" of Prof. B. F. Ramiz Galvão of the University of Rio de Janeiro. He was called on for a speech and he traced the history of the medical department of the university as he has witnessed it develop from small beginnings during the half century of his work there.

Inauguration of Institute of Radiology at Rio.—The new Instituto de Radiologia da Faculdade de Medicina at Rio de Janeiro was formally opened with much ceremony recently. The main floor is devoted to roentgen work and the radium and radioactive service is above. The latter is in charge of Profs. Fernando Terra and E. Rabello, while the chief of the roentgen department is Dr. R. Duque Estrada, assisted by Dr. Alípio Machado. Prof. Aloysio de Castro has been mainly instrumental in securing this addition to the equipment of the medical school.

Deaths in the Profession.—Dr. José M. Jorge, a well known physician and medical writer of Buenos Aires, whose son, José M. Jorge H. is on the editorial staff of the *Revista de la Asociación Médica Argentina*.—Dr. D. de Almeida Sampaio, professor of forensic medicine at the University of Rio de Janeiro, medical expert for the courts and author of various works on medicolegal questions, aged 54.—Dr. J. Testaseca, formerly professor of pathology at the University of Montevideo, aged 84.—Dr. B. Bonifacio, member of the national legislature from Buenos Aires, professor of botany and zoology in the university and vice president of the *Círculo Médico*, aged 32.—Dr. E. Mazzini de Rosario, Argentina, victim of professional infection.—Dr. Santiago Fornós of Chivilcoy, near Buenos Aires, aged 55.—Dr. J. N. Adamo, a leading gynecologist and obstetrician of Mendoza, Argentina.—Dr. J. Viaggio of San Fernando, Argentina, aged 39.—Dr. A. L. Cavo of Buenos Aires, aged 49.

RIO DE JANEIRO LETTER

RIO DE JANEIRO, July 20, 1919.

Yellow Fever

No new case has been registered in Rio de Janeiro. The federal commissions in the northern states are actively engaged in combating the disease. In Bahia new cases have developed. In Alagoas and Sergipe, isolated cases have been reported. Since our last letter commissions have been sent to Pernambuco and Piauí, but up to date no new cases have been reported.

New Hospital

The mayor of the city has opened a credit of \$1,000,000 for the building of a charity hospital. It will be built in the vicinity of the medical school and will be regarded as an annex to that institution. It will contain all modern improvements and will be divided into different pavilions for medicine, surgery, obstetrics, skin diseases, etc.

The National Academy of Medicine

At the meeting, July 3, the National Academy of Medicine elected the following officers: president, Prof. Miguel Conto; vice president, Prof. Aloysio de Castro; first secretary, Garfield de Almeida; second secretary, Belmiro Valverde; speaker, Nascimento Garcel; chairman of the different committees: Antunesello, Pinto Portella, Abreu Fialho, Carlos Sciff, Oscar de Sousa and Orlando Rangel.

Medical Bibliography

The National Academy of Medicine and the Médico-Surgical Society are compiling a catalogue of all medical

publications that have appeared in Brazil within the last hundred years. This catalogue will be distributed in 1920 at the centennial of independence. At the same time a medical congress will be held in Rio de Janeiro under the supervision of Prof. Fernando Magalhães, president of the Sociedade de Medicina e Cirurgia. The program has not yet been definitely.

Child Welfare Congress

A child welfare congress is to be held in Rio de Janeiro in 1920. Its promoter is Dr. Moncorvo, director of the Instituto de Proteção à Infância.

Death of Prof. Diogenes Sampaio

Diogenes Sampaio, professor of chemistry at the Rio de Janeiro University and one of the most prominent doctors in the medicolegal service, is dead. He was only 33 years old and stood high in his profession. The Society of Neurology, Psychiatry and Legal Medicine will hold a special session in his honor.

A New Medical Journal

The first number of the *Archivos de Neurologia e Psiquiatria* has appeared under the direction of Juliano Moreira, A. Austregesilo and Ulysses Vianna. This journal will be devoted principally to neurologic subjects. The *Archivos de Neurologia, Psiquiatria e Medicina Legal* will treat principally of psychiatry and medicolegal questions.

Protection for Workmen

The government has passed a law for the protection of workmen against industrial accidents. A consulting commission of prominent physicians and lawyers has been appointed. The medical profession is represented by the director of the hospital for the insane, director of the medical school and the professors of hygiene and legal medicine.

The Question of Prof. Miguel Pereira's Successor

There are six candidates competing for the professional chair occupied by the late Dr. Miguel Pereira. Each of them has presented a thesis which will be defended before a committee of five professors to be chosen by the members of the medical school. The thesis of Dr. Rocha Vaz, treats of "The Stomach and the Duodenum: Their Pathological Relations"; Dr. Clark's subject is "Syphilis of the Myocardium"; Dr. MacDowell has written on "New Human Spirochete Infections"; Dr. Henrique Duque will present a critical essay on "The Various Tests of Cardiac Efficiency"; Dr. Romeiro will discuss "Medical Semeiology," and Dr. Silva Mello will defend "Diagnosis of the Diseases of the Stomach: A Critical Study."

BUENOS AIRES LETTER

BUENOS AIRES, July 17, 1919.

Typhus Fever

We also had this year some cases of typhus fever in the northern part of the country, but the number was very small and the mortality very limited. This disease has prevailed to some extent in Santiago de Chile and in some other towns of the neighboring country, but apparently it has not crossed the Andes Mountains, and, for the time being, at least, there is no danger of this happening, since the heavy snow has completely interrupted all communication across the mountains.

Public Health Matters

Dr. Emilio Comi's resignation as president of the advisory council of the National Department of Hygiene has been accepted. Dr. Julio Mendez has been chosen to succeed him.

A commission has been appointed to submit a report on the best way to eradicate bubonic plague, a few sporadic cases of which occasionally occur in various parts of the country.

Antituberculosis Conference

The work of organization in anticipation of the second antituberculosis conference, which will be held at El Rosario, September 6-8, is proceeding with great enthusiasm. Various important organizations will be represented at the exposition which will be held in connection with the conference. The subjects for discussion will be: (1) best methods of prophylaxis; (2) compulsory health insurance; and (3) cheap sanitary lodgings.

Congress on Chemistry

The First National Congress on Chemistry was held in this city, July 9-10. The work of the congress scored an even greater success than was expected.

Male Sterility

Drs. Widacovich and Deluca call attention to the large proportion of men whose semen contains no spermatozoa, which amounts to 10 per cent. of those examined. These figures correspond to those recorded in other countries and show that in most cases the husband is responsible for the failure to have children.

Personal

The School of Medicine of the National University of Buenos Aires has submitted to the rector three lists of candidates from which to fill the professional vacancies in the departments of clinical epidemiology, otorhinolaryngology and genito-urinary diseases. The lists are headed by Drs. F. Destefano, E. V. Segura and B. Maraini, respectively. The government has appointed the well known sanitarian, Dr. Emilio Coni, as director of the Santa Maria Sanatorium, which is the most important tuberculosis institution that exists in this country. Dr. Fonso Gandolfo will succeed him at the Buenos Aires dispensary. The School of Medicine has appointed Dr. Alfredo Lanari as dean and Dr. J. B. Gonzalez as member of the council. The Medical Association of Argentina has chosen Dr. Pedro Escudero president. The scientific meetings for the year have already begun at the new quarters of the association.

Exchange of Professors

Lectures have been given in the School of Medicine and before the medical association by Profs. F. Magalhães, Nascimento Gurgel and O. D'Utra Silva from Brazil, and by H. Garcia Lagos and D. Pratt from Uruguay. Other lectures by professors from Uruguay have been announced.

PARIS LETTER

PARIS, July 31, 1919.

Franco-American Medical Relations

In a previous letter (*THE JOURNAL*, Aug. 16, 1919, p. 546) I called attention to the appointment of a committee whose duty it should be to promote closer relations between French and American medical men.

Dr. Tuffier, professor on the faculty of the Paris School of Medicine, was assigned the task of reporting on the desirability of such a union and the best means of bringing it about. At the meeting of the Academy of Medicine, July 22, Dr. Tuffier presented his report. The available means of accomplishing the desired end may be grouped under three heads: exchange of ideas, exchange of students and exchange of scientific material. The first may be realized by Franco-American scientific periodicals published in French and English; by the exchange of all theses printed or made public at the various French and American universities, and by the exchange of professors with a view of securing at first hand the exposition of the results of their investigations. In the matter of exchange of students there are several questions to be considered. The undergraduate students will find it difficult to change countries on account of the necessity of preparing for their examinations. The postgraduate students who will make up the majority of those who will come to France to complete their studies in our clinics and in our laboratories, to visit our specialists and to carry on personal investigations—these are the ones to be chiefly considered from the standpoint of French medical instruction. The exchange of scientific material should include permanent exhibits of French instruments at all the universities of the United States.

The organization recently formed in Paris for the development of Franco-American medical relations will provide for daily instruction distributed throughout the day. Almost all the clinical instructors have evinced an interest in the organization. Furthermore, under the name of *Collège des États-Unis à Paris*, a number of American and French savants have established a bureau of information where Americans arriving in France may secure information in regard to all the courses given or to be given at the various scientific institutions of Paris. This "college" will keep in correspondence with all American universities and all French institutions of learning.

Honmage to Professor Vincent

Under the chairmanship of Dr. Louis Mourier, under-secretary of state for the army medical corps, the friends, admirers and pupils of Dr. Vincent, general medical inspector of the army and professor on the faculty of the *École d'application de médecine et de pharmacie militaires* du Val-de-Grace, were entertained, July 29, at a banquet held in

honor of Dr. Vincent's elevation to the rank of grand officer of the Legion of Honor.

Dr. Mourier gave a sketch of the life of Dr. Vincent and called attention to the part played in the winning of the war by the army medical corps in general and by the guest of honor in particular in saving from death and disease the thousands of French soldiers. M. Edmond Perrier, director of the museum of natural history; Dr. Bandet, surgeon of the *hôpitaux de Paris*, and Dr. François Helme also delivered speeches eulogizing Dr. Vincent.

The Conference of Chemists at London

The delegates of the *Confédération chimique interallée*, representing approximately 30,000 chemists, recently met in conference at London, under the chairmanship of Dr. Charles Mourou, professor of organic chemistry in the *Collège de France* and a member of the Academy of Science. Some important business was transacted at this meeting. One of the most important resolutions concerns adoption of a common system of bibliographic documentation which will be carried out in England and in France.

At the close of the conference a delegation proceeded to Brussels to get in touch with the committee of the *Conseil international de recherches* with which the *Confédération chimique interallée* is to be incorporated under the name of the *Union internationale de la chimie pure et appliquée*. The next conference will be held in Italy in June, 1920.

Establishment of a Place of Refuge for the Homeless

Near the outside fortifications of Paris a place of refuge destined to harbor temporarily the inhabitants of the devastated regions has been established. It is intended for refugees who are seeking to return to their homes and also for demobilized soldiers who are without shelter. Six barracks have been selected to furnish lodging. In the vicinity of the barracks there have been erected: a bath-house, a lavatory, an infirmary, a guard-house and a recreation hall for children, etc.

Personal

Dr. Lambert, professor on the faculty of the Nancy School of Medicine, has recently been transferred to the professorship of physics as applied to medicine.

Death of Dr. Albert Gouget

The death of Dr. Albert Gouget, a physician of the *hôpitaux de Paris*, recently appointed professor of general pathology and therapeutics at the Paris School of Medicine, has been announced.

Death of Dr. George Bertillon

Dr. George Bertillon, president of the *Fédération des Syndicats médicaux*, died recently at Maisson-Laffitte (department of the Seine-et-Oise). He was a brother of Alphonse Bertillon, the inventor of the system of anthropometric measurements used extensively in criminology, and also of Dr. Jacques Bertillon, director of the medical and surgical statistics bureau of the army.

LONDON LETTER

LONDON, Aug. 5, 1919.

The Presentation to Sir William Osler

The presentation to Sir William Osler of a collection of essays on the eve of his seventieth birthday at the house of the Royal Society of Medicine has been announced in a previous letter. A large audience, which included many leaders of the profession and the heads of the medical departments of the army and navy, assembled. The function was a remarkable, indeed a unique one, for the presentation was made by Sir Clifford Allbutt, the Nestor of the profession. Thus were brought together as the principal actors of the scene the Regius professors of the two great English universities, the greatest medical teachers of the day, each distinguished not only by medical eminence but by scholarship and literary power. Sir Clifford Allbutt, who claimed to be one of Sir William Osler's oldest friends, said that in him we saw the fruitfulness of the marriage of science and letters, and the long inheritance of a culture which amid the manifold forms of life and through many a winter and summer has survived to inspire and adorn a civilization which so lately narrowly escaped the fury of the barbarian. Sir William Osler, who at times spoke with emotion, said that the pride a man might justly feel at this demonstration of affection by colleagues on both sides of the Atlantic was deepened by two circumstances—the fact that amid so much mental

and physical tribulation his friends should have had the courage to undertake this heavy two-volume task, and that the honor was received at the hands of his brother Regius. Paying Sir Clifford Allbutt a graceful compliment, he said that to him had been given in fuller measure than to any other person in our generation a rare privilege: to him, when young, the old listened as eagerly as do now, when old, the young. The long list of contributors to the volumes recalled his vagrant career: Toronto, Montreal, London, Berlin and Vienna as a student; Montreal, Philadelphia, Baltimore and Oxford as a teacher. "To have had the benediction of friendship follow one like a shadow, to have always had the sense of comradeship in work, without the petty pinpricks of jealousies and controversies, to be able to rehearse in the sessions of sweet, silent thought the experiences of long years without a single bitter memory, fill the heart with gratitude. That three transplantations have been borne successfully is a witness to the brotherly care with which you have tended me. Loving our profession, and believing ardently in its future, I have been content to live in it and for it. A moving ambition to become a good teacher and a sound clinician was fostered by opportunities of an exceptional character, and any success I may have attained must be attributed in large part to the unceasing kindness of colleagues and to a long series of devoted pupils whose success in life is my special pride."

The contributions to the volumes number 150, and are from the pens of professional leaders on both sides of the Atlantic—physicians, surgeons, physiologists, anatomists, pathologists and historians. In keeping with Sir William Osler's interests, many of the subjects are educational. Among those contributed in this country are the introduction, by Sir Clifford Allbutt; "The Oxford Museum," by Dr. T. Dyke Acland; "The Oxford Medical School in the Eighteenth Century," by Dr. Arnold Chaplin; "The Problem of Graduate Medical Study in London," by Dr. J. G. Adams; "The Organization of Medical Research," by Sir Walter Morley Fletcher; "The Laboratory and the Ward," by Sir A. E. Garrod; "The Cradle of the Hunterian School," by Prof. Arthur Keith, and "Ideals for a Medical Library," by Mr. J. V. W. MacAlister.

The Law and Professional Secrecy

Recently (THE JOURNAL, July 12, p. 124) I called attention to a case in which a girl was prosecuted for concealment of birth. A physician called in did not think it was his duty to inform the police, as it would have been a breach of professional confidence. The judge took occasion to lecture the physician, telling him that he was wrong, as there could be no professional confidence in criminal cases. If a patient cut another person's throat it would be his duty to inform the police. There was no difference between the two cases. This view is certainly not accepted by the medical profession, as a letter to the *British Medical Journal* from Sir John Tweedy, president of the Medical Defense Union, shows. He states that the council of the union is unable to accept the analogy as a fair one. The standpoint of the medical profession has more than once been challenged by the legal profession. The council nevertheless maintains that the duty of a physician to his patient is paramount, and advises any member seeking guidance that any communication made to him by a patient and any information acquired in such attendance are confidential, and that without the authority of the patient a physician is precluded by the canons of his profession from disclosing such information.

The British Medical Association Rejects Trade Unionism

At the annual meeting of the representatives of the British Medical Association, the question of trade unionism came up again. The following resolution was moved by the Bournemouth representative: "That, although the council of the association should be given every opportunity of circulating its reasons against the organizing of the profession on trade union lines, it should not endeavor to prevent such members of the association as may not be convinced by the arguments used from joining any other body which is attempting to combine the profession on such lines, and should encourage conferences with all bodies, representing members of the profession, to secure joint action to obtain satisfactory conditions of practice." The resolution, of course, referred to the Medicopolitical Union, a body described previously in THE JOURNAL. An animated discussion followed in which the hostility of the union to the association, while at the same time proffering cooperation, was the subject of comment. The chairman of the council said there was scarcely a single line of activity in which the union had not vilified the association. The motion was rejected by a majority of 75 to 17.

Marriages

HERBERT ROWELL STOLTZ, Capt., M. C., U. S. Army, Stanford University, California, on duty with the American Army of Occupation, to Miss Sarah E. Adams of St. Joseph, Mo., in Paris, recently.

CLARENCE PENNELL BAXTER, Major, M. C., U. S. Army, on duty in Porto Rico, to Miss Mary Lyons Hartley of Washington, D. C., August 20.

MICHAEL NAVIER SULLIVAN, U. S. P. H. S., Spartanburg, S. C., to Miss Rachel Brook of Carrollton, Ga., at Asheville, N. C., July 28.

RICHARD HORACE HOFFMAN to Miss Martha Janet Beecher Wyndham, both of New York City, at Pelham Bay, N. Y., August 10.

WILLIAM HART ELMER, Rockford, Ill., to Miss Lenore Crompton of Beavercreek, P. Q., Can., August 12.

OLIVER PAXTON BOARD, Birmingham, Ala., to Miss Helen Shaw of England, at Detroit, recently.

JRA LINCOLN FETTERHOFF, Baltimore, to Miss M. Alice Burton of Washington, D. C., August 13.

JEAN FELIX PICARD, Lausanne, Switzerland, to Miss Jeanette Ridlon of Chicago, August 19.

JOSEPH MICHAEL BLAKE, Chicago, to Miss Cecile Mary Schug of Moline, Ill., July 12.

HORACE ERNEST AYERS to Miss Muriel Randle Peck, both of New York City, August 6.

RALPH L. MAXWELL to Mrs. Maude M. Maxwell, both of Little Rock, Ark., August 8.

HAROLD ALBERT BAUMANN to Miss Craita Reiss, both of Sheboygan, Wis., recently.

Deaths

Henrietta Martha Thomas, Baltimore: Woman's Medical College of Baltimore, 1904; aged 40; a member of the staff of the Thomas Wilson Sanatorium for Children, Mount Wilson, Baltimore County; who went to England in 1914, and associated herself with the Society for the Relief of Destitute Aliens, and after the United States entered the war, devoted herself to work among the destitute alien children in England; died suddenly in York, England, August 4, from heart disease.

Charles L. Gregory, Greenville, Texas: University of Tennessee, Nashville, 1890; once city physician of Greenville; for two terms president of the Hunt County (Texas) Medical Society; formerly superintendent of the North Texas Insane Asylum, Terrell, and recently appointed superintendent of the new state hospital at Rust; president and superintendent of the Parkview Retreat, Greenville; died suddenly in that institution, August 11.

Herman Edward Street, Brooklyn: New York Homoeopathic Medical College, 1892; aged 73; visiting dermatologist to the Cumberland Street Hospital, Brooklyn; a member of the consulting staff of the Brooklyn Memorial Hospital for Women, and an examiner in lunacy; died in the Peck Memorial Hospital, Brooklyn, August 18, two days after an operation for peritonitis.

Arthui Meeker Collier, Utica, N. Y.: College of Physicians and Surgeons, 1889; aged 54; from 1891 to 1895 physician at the Binghamton State Hospital; and then for a year first assistant physician at the New York State Hospital, Ogdensburg; died in St. Luke's Hospital, Utica, August 4, from paralysis.

John Russell Dickson, Gettysburg, Pa.: University of Pennsylvania, Philadelphia, 1880; aged 60; physician to the Adams County Poor Farm for nine years; county medical inspector and physician in charge of the State Tuberculosis Dispensary since 1908; died at his home, August 13, from cerebral hemorrhage.

John Henry Barnes ♦ Enid, Okla.: Hospital College of Medicine, Louisville, 1901; aged 47; secretary of the Garfield County Medical Society in 1908; a specialist on diseases of the eye, ear, nose and throat; died at a hospital in Minneapolis, August 8, from valvular heart disease.

♦ Indicates "Fellow" of the American Medical Association.

Julia Pauline Larson, San Francisco; University of California, San Francisco, 1900; resident physician of the Children's Hospital, San Francisco, for five years, and a member of the surgical staff for eight years; died in Stephenson, Merced County, Calif., July 17.

William R. Rodes, Mexico, Mo.; Jefferson Medical College, 1859; aged 83; a member of the Missouri State Medical Association; once superintendent of State Hospital No. 3, Nevada, Mo.; died at his home, August 4, from valvular heart disease.

John A. Pettit, Buffalo; University of Buffalo, 1874; aged 76; a member of the Medical Society of the State of New York; from 1895 to 1899 deputy health commissioner of Buffalo; died at his home, August 6, from pernicious anemia.

Mary Blair Moody ♦ West Haven, Conn.; University of Buffalo, N. Y., 1870; aged 82; the first woman graduate of the medical department of the University of Buffalo; a botanist of high repute; died at her home, August 18.

John Ruggles Greenleaf, Gardner, Mass.; College of Physicians and Surgeons in the City of New York, 1865; aged 78; a member of the Massachusetts Medical Society; died at his home, June 8, from acute dilatation of the heart.

Thomas Hagarty, East St. Louis, Ill.; St. Louis College of Physicians and Surgeons, 1890; aged 54; a member of the Illinois State Medical Society; was run over and killed by an interurban car in East St. Louis, August 14.

Franklin Harmon Godfrey ♦ Bloomington, Ill.; Miami Medical College, Cincinnati, 1877; aged 71; president of the McLean County Medical Society from 1900 to 1902; died at his home, August 8, from cerebral hemorrhage.

Ulysses Grant Galloway, South Bend, Ind.; Kentucky School of Medicine, Louisville, 1893; aged 52; a member of the Indiana State Medical Association; died at his home, August 12, from malignant disease.

Lyell J. Lescher, Mount Carmel, Ill.; Jefferson Medical College, 1877; aged 62; a member of the Illinois State Medical Society; died at his home, July 21, from ulcerative endocarditis following influenza.

Pedro Florentine Francke, New York City; College of Physicians and Surgeons in the City of New York, 1892; aged 53; died in the Peter Bent Brigham Hospital, Boston, August 19.

Fred Heller ♦ Brownstown, Ind.; Kentucky School of Medicine, Louisville, 1898; aged 51; a member of the Brownstown school board; died suddenly, August 11, from heart disease.

Edward Baron Chandler, Moncton, N. B.; College of Physicians and Surgeons in the City of New York, 1871; aged 71; died at his home, May 13, from valvular heart disease.

Howard Cecil Sarver ♦ Lieut., M. C., U. S. Army, Charleston, W. Va.; American College, St. Louis, 1912; aged 31; died at his home, July 24, from cerebral hemorrhage.

Joseph Frank Meagher, San Francisco; University of California, San Francisco, 1902; aged 42; died at his home, August 15, from endocarditis following influenza.

Edward McDonald ♦ Cuba, Wis.; Rush Medical College, 1879; aged 68; a member of the Grant County board; died at his home, August 7, from cerebral hemorrhage.

Lewis Lorenzo Lacey, Austin, Texas; Bellevue Hospital Medical College, 1874; aged 68; died in the City Hospital, Austin, May 11, from cerebral hemorrhage.

John Marquand Wagner, Newman, Ill.; Bellevue Hospital Medical College, 1878; aged 76; died at his home, June 10, from chronic diffuse nephritis.

Nathan L. Bailey, Lake Preston, S. D.; Keokuk (Iowa) Medical College, 1892; aged 58; once mayor of Lake Preston; died at his home, August 5.

Carl Herman Stein ♦ Pittsburgh; University of Pittsburgh, 1912; aged 44; died at the home of his sister in Pittsburgh, August 5, from pneumonia.

Marcus Claude Terry ♦ Brighton, Iowa (license, years of practice, Iowa, 1886); aged 75; a practitioner since 1864; died at his home, recently.

Robert S. Boshier, Jr. ♦ Richmond, Va.; Medical College of Virginia, Richmond, 1900; aged 45; died at his home, July 20.

William Harrison Lane, Miller, S. D.; Bellevue Hospital Medical College, 1882; aged 75; died at his home, in July.

George C. Somers, Los Angeles; Rush Medical College, 1880; aged 77; died at his home, July 6.

The Propaganda for Reform

IN THIS DEPARTMENT APPEAR REPORTS OF THE COUNCIL ON PHARMACY AND CHEMISTRY AND OF THE ASSOCIATION LABORATORY, TOGETHER WITH OTHER MATTER TENDING TO AID INTELLIGENT PRESCRIBING AND TO OPPOSE MEDICAL FRAUD ON THE PUBLIC AND ON THE PROFESSION

S. S. S.

The One-Time Cure for "Contagious Blood Poison" Becomes a Remedy for Rheumatism

As a general thing, federal laws get action where state laws fail. One has only to call to mind the innocuousness of the average state law—there are happy exceptions—governing the sale of food and drugs, and compare it with the federal law covering much the same field, to realize the advantages of national legislation over state legislation. Occasionally it happens that the states are able to bring about reforms in the interest of the public that the federal government has failed to achieve. Readers of THE JOURNAL will remember the case referred to a few years ago regarding the result of North Dakota's net-weight law. Before there was any national legislation on the subject of requiring package goods to be plainly labeled with the net-weight of the contents, North Dakota had such a law, and what is more important, enforced it. As a result, one of the largest manufacturers of biscuits withdrew its business from that state rather

S. S. S. is not only a certain cure for Syphilis but is the one absolutely safe remedy. It contains no strong minerals to damage the system, but is made entirely of roots, herbs and barks of healing, cleansing nature.

We offer \$1,000 for proof that S. S. S. contains a particle of mineral in any form.

**• THE SWIFT SPECIFIC CO.,
ATLANTA, GA.**

A page from one of the older booklets sent out by the Swift Specific Company. At that time the concern made no secret of the claim that S. S. S. was offered as "the one absolutely safe" and "certain cure for syphilis."

than comply with the law. The people of North Dakota, however, were favorably situated to go into the biscuit making business themselves, and did so, putting out their products in compliance with the laws of their own state. After a few years the concern which had withdrawn its business from North Dakota reentered that state with its products labeled in accordance with the requirements of the North Dakota law. The important point is that the people in every state of the Union benefited by the reforms brought about by the law of one state.

Still another instance of a state law benefiting the nation arose in the case of the prosecution against "Hall's Catarrh Cure" by the state of Nebraska. For years after smaller and less powerful "patent medicine" makers had been forced by the federal authorities to remove the word "cure" from their trade packages, the Hall nostrum was sold as a "cure." Finally the company was prosecuted under the Nebraska laws. Later this item appeared in a drug journal:

"Cheney & Co., of Toledo, Ohio, asked leave to dismiss their appeal to a district court in Nebraska, in the action of the state food and drug department to have 'Hall's Catarrh Cure' declared misbranded in the use of the word cure. The company also expressed its purpose of changing the name of its preparation to 'Hall's Catarrh Medicine.'"

Soon thereafter it became "Hall's Catarrh Medicine" all over the United States; it continued to be a "cure" in Canada for some years.

Now comes the state of Louisiana in the rôle of a possible national benefactor. That state has a law prohibiting the sale

of venereal disease remedy—except on the written prescription of a licensed physician. In May of this year the Bureau of Venereal Diseases of the Louisiana State Board of Health notified the druggists of Louisiana that the sale of "S. S. S." ("Swift's Syphilitic Specific" or "Swift's Sure Specific") would meet with the same law enforcement measures as were being waged against any venereal disease nostrum. The immediate result of this notice was a letter sent to various drug stores in Louisiana by the sales manager of the Swift Specific Company, breathing, alike, injured innocence and defiance. The company was inexpressibly shocked to learn that its product should be classed as a venereal remedy. Said the sales manager:

"We wish to state emphatically that this is a misrepresentation of facts. Please accept this letter as our positive guarantee that S. S. S. is not recommended or advertised as a Venereal medicine. We challenge any one to find on our package or in any of our advertising in the newspapers or elsewhere any statement or claim that S. S. S. is good for Venereal diseases."

"It is difficult to understand why such a claim could be made, and would suggest that you challenge, by letter, the right of the State Board of Health to forbid you to sell S. S. S., or anything else, on such a pretext. Doesn't it appear very peculiar that they should construe S. S. S. to be a Venereal remedy, and prevent you from selling it, when it is positively not so advertised or recommended? In no other state has its sale ever been questioned."

The letter closed with a suggestion to the effect that the druggist go ahead and sell S. S. S., and that they would be supported by the company. Was it "very peculiar" that the Bureau of Venereal Diseases of the State Board of Health of Louisiana "should construe S. S. S. to be a Venereal remedy?" Let us see: It was only a few years ago that

Letters that have been sent out by the Swift Specific Company during the past few years, and which THE JOURNAL has in its files—letters that were written to individuals who had indicated to the company that they had syphilis—have made such claims as:

"In S. S. S. we have the only vegetable antidote to Syphilis that has ever been discovered . . ."

"For more than 40 years S. S. S. has been recognized as the one remedy for Syphilis. Thousands upon thousands have been cured through its use."

In one of the older booklets, a portion of which is reproduced with this article, the claim appeared in black, bold-faced type:

"S. S. S. is not only a certain cure for Syphilis, but is the one absolutely safe remedy."

We could continue to quote statement after statement, made in the S. S. S. advertising, advocating both by the most direct of statements and also by inference the claim that S. S. S. is a cure for syphilis.

But the Swift Specific Company evidently saw—in the action of the authorities in Louisiana—the hand-writing on the wall and a few weeks ago the State Board of Health of Louisiana received this letter from the general manager of the Swift Specific Company:

"In accordance with a resolution adopted by the Board of Directors of the Swift Specific Company, a copy of which resolution I am herewith enclosing you, the S. S. S. Company, through me as the Manager of said company, does hereby guarantee that in every advertisement published in the State of Louisiana, as well as on the labels and cartons containing the product of the Swift Specific Company, there will be a statement in the same size type as the rest of their advertising that S. S. S. is not sold for the treatment, for the cure or as a remedy for venereal diseases."

This letter was dated June 26, 1919. On Aug. 20, 1919, a bottle of S. S. S. was purchased in Chicago. The drug clerk was asked particularly whether it was "new stock," he declared that they "got it in a few days ago." The carton in which this bottle came still holds out by inference the claim that S. S. S. is a remedy for syphilis. Thus:

"\$1000 is offered for proof that it contains one particle of Mercury, Potash, Arsenic, or any other mineral drugs."

"Persons who for any reason do not wish to use mercury, potash, arsenic, or other minerals, may take S. S. S. with the full assurance that it contains none of these ingredients."

On the circular that came with the bottle—"adopted and approved" Jan. 1, 1918—there is this statement:

"S. S. S., being compounded of vegetable plants, and having no Mercury, Potash, Arsenic, or other mineral drugs in its composition, may be taken for an indefinite period."

There is no statement anywhere to the effect that "S. S. S. is not sold for the treatment, for the cure or as a remedy for venereal diseases." Does this mean that the Swift Specific Company is going to put up special cartons and advertising copy for the state of Louisiana, or does it mean that the bottle purchased a few days ago in Chicago had been in the hands of a jobber for some months?

On Aug. 21, 1919, a bottle of S. S. S. was purchased in Louisiana. The \$1,000 "offer" quoted from the carton of the Chicago sample, read in the case of the Louisiana sample, thus:

"\$1000 is offered for proof that it contains one particle of mineral drugs."

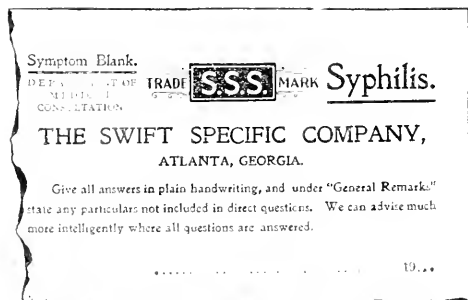

On the circular that came with the bottle—"adopted and approved" June 25, 1919 there is this statement:

"S. S. S. being compounded of vegetable plants and having no Mercury, Potash or other mineral drugs in its composition may be taken for an indefinite period. Its effect is recognized as being beneficial to the system."

The circular also bore the following paragraph:

"S. S. S. is a mechanical agent indicated in the treatment of Rheumatism, Catarrh, Malaria, Eczema and Skin Diseases, arising from conditions of the Blood. It has been extensively employed in the treatment of such diseases. Under certain laws, remedies and treatments for venereal diseases must be sold on written prescription of a licensed physician. This preparation is not sold for such diseases."

The paragraph just quoted also appeared on a small sticker pasted on the carton.

Photographic reproduction (reduced) of part of a "Symptom Blank" sent out in November, 1916, by the S. S. S. Company to a person who wanted medical advice in the treatment of syphilis.

S. S. S. was boldly and blatantly heralded in large display newspaper advertisements as a "cure" for syphilis, or, as it was more euphemistically described in the advertisements, "Contagious Blood Poison." As newspapers became a little more careful of the type of "patent medicine" copy they would accept, the Contagious Blood Poison advertisements were semi-medaled while "Rheumatism," "Catarrh," and "Impure Blood" were played up as the ailments for which S. S. S. was recommended. In the trade packages, however, the purchaser of S. S. S. was urged to write for the "special book on the blood," which he was told "goes deeply into the subject of mercury, iodid of potash, arsenic and other mineral drugs." Those who sent for the booklet learned from it that it would "enable one to properly treat syphilis under the use of S. S. S. together with such medical advice as we give gratis by correspondence." They learned further from this booklet that:

"... those who eliminate you, so fall into the clutches of that pestiferous, Syphilis, which has caused and is causing untold agony and suffering to the victims of S. S. S. who have been led to it."

According to this booklet, further, S. S. S. had:

"... become a household necessity in various forms of blood poisoning, and especially effective in the most destructive and distressing of all forms of it, the contagious poison, known as Syphilis."

Years ago S. S. S. was solemnly announced as a cure for cancer: "That S. S. S. cures cancer is a fact that experience has placed beyond doubt." But public opinion has long frowned on the "cancer cure" business and for some years nothing seems to have appeared in the S. S. S. literature regarding its alleged curative effects in that disease. The public is now waking up to a fact that the medical profession has been attempting to hammer home for years: the self-treatment of venereal disease is not only fraught with danger to the individual, it is a menace to the community.

Public opinion has reached the stage at which it will support laws prohibiting the sale of nostrums for the self-treatment of venereal disease; this, too, in spite of the fact that the "patent medicine" interests insist that there is no valid reason why the individual should be deprived of the right to buy and use remedies for the self-treatment of venereal disease. Such being the case, S. S. S. will perforce drop its long advertised claim as a remedy for syphilis. Even so it will not be possible to eliminate from the consciousness or subconsciousness of thousands of individuals who have read the advertisements in the past or have been given the

INTRODUCTION

It has become necessary for us to issue another edition of our treatise on Contagious Blood Poison, and we avail ourselves of the opportunity to return our thanks to the public for its appreciation of S. S. S., and to felicitate ourselves that we are able to do so much towards abating the ravages of disease among mankind.

Especially is this true among those unfortunates who have fallen into the clutches of that great enemy, Syphilis, and who may be said to have been without an advocate to point out the virtues of S. S. S. were made known to them. From a small beginning it has made its way in popular favor, gradually overcoming the prejudice against proprietary remedies, and inspiring hope in the breasts of those who had ceased to hope, till now it has become a household necessity in various forms of blood poisoning, and a remedy of the most destructive and destructive disease of the system, the contagious venereal disease. (One after another, who have been rescued from untimely graves or lives of hopeless misery, have joyfully imparted the news to their despairing comrades, and now there is a great army ready to sing its praises and carry forward its victorious standard.

The necessity for this new edition is found in the fact that so many are seeking to gain a knowledge of this wonderful Blood Purifier, and are writing

For special directions, see page 25.

Photographic reproduction (reduced) of page 1 of a booklet sent to the same individual who received the "Symptom blank," a part of which is reproduced with this article. Note the statements which we have underlined.

information by word of mouth, the belief that S. S. S. is a remedy for syphilis! There are on the market today a score of worthless nostrums purchased by foolish women in the belief that they are abortifacients; yet in no instance do the manufacturers of these products dare specifically to announce them as such. The hundreds of thousands of dollars expended in the past by the Swift Specific Company to bring home to a certain part of the population the alleged fact that S. S. S. is a "purely vegetable" cure for "Contagious Blood Poison" cannot be wiped out of the public consciousness by the declaration on the part of the manufacturers that "S. S. S. is not sold for the treatment, for the cure or as a remedy for venereal diseases." Furthermore, it is worth noting that the manufacturers do not actually disclaim their previous pretenses. They do not come out boldly and say "S. S. S. will not cure venereal disease." All they do is more cautiously to announce that it is "not sold for such diseases."

The principle on which most "patent medicines" are exploited seems to be: Lie when you can; tell as little of the truth as you must.

Correspondence

SIR WALTER SCOTT'S LAMENESS

To the Editor:—Reference has recently been made, by Crookshank and others, to the childhood lameness of Sir Walter Scott as a definite case of infantile poliomyelitis. The attack came on in 1773, when Scott was about 18 months old, some ten years before the publication of Michael Underwood's well-known account of the disease (1784). The details, as given in Lockhart's Life of Scott, may be not uninteresting to American physicians:

I showed every sign of health and strength until I was about eighteen months old. One night, I have often been told, I showed great reluctance to be caught and put to bed, and after being chased about the room, was apprehended and consigned to my dormitory with some difficulty. It was the last time I was to show such personal agility. In the morning I was discovered to be affected with the fever, which often accompanies the cutting of large teeth. It held me three days. On the fourth, when they went to bathe me as usual, they discovered that I had lost the power of my right leg. My grandfather, an excellent anatomist as well as physician, the late worthy Alexander Wood, and many others of the most respectable of the faculty, were consulted. There appeared to be no dislocation of the spine, blisters and other topical remedies were applied in vain. When the efforts of regular physicians had been exhausted, without the slightest success, my anxious parents, during the course of many years, eagerly grasped at every prospect of cure which was held out by the promise of empires, or of ancient ladies or gentlemen who conceived themselves entitled to recommend various remedies, some of which were of a nature sufficiently singular. But the advice of my grandfather, Dr. Rutherford, that I should be sent to reside in the country, to give the chance of natural exertion, excited by free air and liberty, was first resorted to, and before I have the recollection of the slightest event, I was, according to this friendly counsel, an inmate in the farmhouse of Sandy-Knowe.

It is here that Sandy-Knowe, in the residence of my paternal grandfather, already mentioned, that I have the first consciousness of existence; and I recollect distinctly that my situation and appearance were a little whimsical. Among the old remedies resorted to to aid my lameness, some one had recommended that so often as a sheep was killed for the use of the family, I should be stripped and swathed up in the skin, warm as it was flayed from the carcass of the animal. In this Tartar-like balishment I well remember my grandfather, a venerable old man with white hair, used every exertion to make me try to crawl. I also distinctly remember the late Sir George MacDougall of Makerston, father of the present Sir Henry Hay Mac Dougall, joining in this kindly attempt. He was, God knows how, a relation of ours, and I still recollect him in his old-fashioned military habit (he had been colonel of the Greys), with a small cocked hat, deeply laced, and embroidered scarlet waistcoat, and a light-coloured coat, with milk white laces tied in a military fashion, kneeling on the ground before me, and dragging his watch along the carpet to induce me to follow it. The benevolent old soldier and the infant wrapped in his sheepskin would have afforded an odd group to uninterested spectators. This must have happened about my third year, for Sir George MacDougall and my grandfather both died shortly after that period.

I was in my fourth year when my father was advised that the Bath waters might be of some advantage to my lameness. My affectionate aunt, although such a journey promised to a person of her retired habits anything but pleasure or amusement, undertook as readily to accompany me to the wells of Bath, as if she had expected all the delight that ever the prospect of a water cure held out to its most impatient votaries. My health was by this time a good deal confirmed by the country air, and the influence of that unimpeachable and unflagging exercise to which the good sense of my grandfather had subjected me; for when the day was fine, I was usually carried out and laid down beside the old shepherd, among the crags or rocks round which he fed his sheep. The impetuosity of a child soon inclined me to struggle with my nurmary, and I began by degrees to stand, to walk, and to run. Although the limb affected was much shrunk and contracted, my general health, which was of more importance, was now strengthened by being frequently in the open air, and, in a word, I who in a city had probably been condemned to hopeless and helpless decrepitude was now a healthy, high-spirited, and, my lameness apart, a sturdy child. *non erat discipulus, sed magister.*

The shrinking and contraction of the limb is strongly suggestive of the affection described by Underwood and Heme. There have even been apparent figurative of the disease in art, for instance, on an Egyptian stele of the eighteenth dynasty in the Carlsberg Glyptothek at Copenhagen (*Bull. Soc. franc. d'hist. de méd.*, Paris, 1903: 408, 1911); or the picture of the paralytic beggar boy by Ribera in the Vienna gallery. In a footnote to the article on Sir Walter Scott in the ninth edition of the *Encyclopædia Britannica* (p. 545), Dr. Charles Creighton says that Scott's primary trouble was "a swelling at the ankle, and either consisted in or gave rise to arrest of the bone-forming function along the growing line of cartilage which connects the lower epiphysis of each of the two leg-

bones with its shaft. . . . The limb would have been blighted very much more if the arrest of growth had taken place at the upper epiphysis of the tibia or the lower epiphysis of the femur. The narrowness and peculiar depth of Scott's head point to some more general congenital error of bone-making allied to rickets, but certainly not the same as that malady. The vault of the skull is the typical "scaphoid" or boat-shaped formation, due to premature union of the two parietal bones along the sagittal suture." Creighton goes on to say that this synostosis of cranial bones is characteristic in microcephalous idiots, and he relates that an eminent French anthropologist, who saw a microcephalic skull in the Cambridge Museum of Anatomy, pointed to the scaphoid vault of the crown and the effaced sagittal suture, with the exclamation: "Voilà Walter Scott!" Scott's brain was found to be small in size after death, a fact of little moment in itself, since there is apparently no special relation between cranial capacity, brain weight and ability. Turcotte and Cuvier had the largest and heaviest brains, Shelley, Scott, Mozart, Gambetta and others, among the smallest.

F. H. GARRISON, M.D., Washington, D. C.

"THE ADMINISTRATION OF ARSPHENAMIN"

To the Editors:—In the letter by Director McCoy of the Hygienic Laboratory, "The Administration of Arspheamin" (THE JOURNAL, July 12, 1919, p. 130), there appears the statement that when only one of several physicians using arspheamin of the same batch "registers complaint as to the quality of the drug, and the others use it with satisfaction, there seems to be no other conclusion than that the mode of administration in the exceptional case was at fault."

In such case I believe there is at least one other justifiable conclusion: that arspheamin, perhaps insufficiently dried, will in the course of six months or a year develop toxic by-products in the ampule, and that the amount present will vary with the length of time that elapses before the contents are used and perhaps according to the conditions under which it has been stored. Conceivably such a product may pass the biologic tests at the time of manufacture, and later produce distressing symptoms in human beings. Dr. Hugo Freund, who had been using the "product which enjoys a particularly high reputation" with entire satisfaction, recently reported to me four successive delayed reactions in as many patients. The symptoms were vomiting and an itching dermatitis, occurring from one to four days after administration of the drug. An ampule was examined and was found to be sound, but the contents gave a solution with the characteristic gum-metal tinge due to oxidation. It can be readily demonstrated that arspheamin will shed metallic arsenic when it has become oxidized, whereas the unchanged base will not do so when reduced with zinc and hydrochloric acid. The so-called nitritoid reactions may also be induced by factors other than dilution and alkalization, however important the latter may be. Ehrlich and Berthelm, in 1912, stated that "salvarsan" contained about 7 per cent. of methyl alcohol, after having been dried for two hours, and in 1918 the two brands of American arspheamin examined by me were similarly found to contain it. I believed then, as I do now, that this alcohol acts on the base in the ampule, and that a certain amount of methyl arsin may thus accumulate, and when intravenously injected may cause the nitritoid reactions; and according to the amount that may thus have accumulated, the rapidity of injection and the concentration of the solution, cardiac paralysis may result. Kober, working independently, has reached much the same conclusions, and has further succeeded in preparing arspheamin, free of methyl alcohol, and according to his tests of a lower toxicity. Neo-arspheamin can be made without the use of methyl alcohol, and this undoubtedly explains the long series of injections reported by Dr. H. McIlure Young (THE JOURNAL, July 12, p. 131), who used a French brand, in high concentrations, without reactions.

In the decade that has elapsed since the introduction of arspheamin into therapeutics, the majority of practitioners surely should have been able to master the technique of measur-

ing water and counting drops of alkali according to printed directions. I believe there is room for improvement in the drug itself as well as in our methods of administering it.

JOHN B. RIEGER, M.D., Detroit.

STETHOSCOPE OR STETHOPHONE

To the Editor:—Referring to your editorial on Laennec and the stethoscope, you give the Greek word *skotēiv* to mean "to examine." Could not the word also be translated "to view" or "to observe"? The ending "scope" being associated with all instruments used for examining by sight, as the telescope, microscope, spectroscope, etc., it seems an error to couple it with a sound-transmitting instrument, the ending "phone" or "fone" being universally used in the latter connection, as telephone, microphone, etc.

EUGENE KERR, M.D., Towson, Md.

[COMMENT.—As stated, *skotēiv* may mean "to view"; in fact, that is the ordinary meaning of the word, while "to look to, to consider, to examine" are common figurative meanings. Compare, in this connection, "to look into" in English, which has also the figurative meaning "to examine into"; as, for instance, "I will look into the matter." With regard to the question as to whether it would be more accurate to call the stethoscope a stethophone: The term "stethophone" has already been proposed by others who regard it as a more accurate designation for a sound-transmitting instrument, and it will be found duly listed in "The American Medical Dictionary." In regard to *phōivēiv*, the second component part of stethophone, it may be said that it means primarily "to produce a sound or to speak." It does not seem to mean "to sound," as we speak of sounding the depths of the sea; if it did, "stethophone," chest sounder, might be very appropriate. A "stethophone," then, signifies an instrument for making the chest to sound or to resound. Since it does make almost inaudible sounds distinctly audible it may perhaps be said, figuratively speaking, to make the chest resound; but, from an actual standpoint, it has no appreciable effect on the quality of the chest sounds per se. The word "microphone" might have been appropriately used for the stethoscope, since it is an instrument for magnifying sounds. As to the term "stethoscope," since the instrument in question, to which Laennec himself gave the name, serves to examine the chest, it does not seem inappropriate to call it a "stethoscope," a chest examiner. When, however, the same instrument is used to examine the arteries or the beat of the fetal heart, one has the feeling that the name "stethoscope" is not a broad enough term. It might well be termed a "phonoscope," an instrument for testing sounds, or a "microphonoscope," an instrument for examining scarcely audible sounds, or a "stethophonoscope," when the instrument has been especially adapted for examining the sounds of the chest; or suffering humanity could, if necessary, be inflicted with the term "stethomicrophonoscope," which would mean an instrument for examining the scarcely audible sounds of the chest. This term ought to be "descriptive" enough to satisfy anybody. For short, "stethoscope" does very well. It may be added that the modern Greeks have accepted the term "stethoscope," since they call the instrument *σθητοσκόπιον*.—E.B.]

CENTENARY OF THE STETHOSCOPE

To the Editor:—Recently, in looking over a first edition of Laennec's "Auscultation Médiate" I noticed that it bore the date 1819. The first issues of the book appeared in Paris in September of that year—just a hundred years ago. An editorial in THE JOURNAL of August 9 emphasizes this fact. Should there not be some general recognition of this anniversary by the American medical profession? The centenary of the stethoscope! It is at least an opportunity to acknowledge gracefully a part of the great regard we must feel for all France just now, and particularly, with us, for the members of the medical profession in France. If no general act can be accomplished, I would suggest that the various county societies have a Laennec program early in their fall meetings.

LOGAN CLIFDENING, Kansas City, Mo.

Instructor in Physical Diagnosis, University
of Kansas School of Medicine.

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

HEALTH STATUS AND HEALTH PECULIARITIES OF THE JEWISH RACE

To the Editor:—Please suggest a list of books, magazine articles, statistical data, etc., dealing with the question of health status and health peculiarities of the Jewish race in all countries. Any material dealing with the susceptibilities and tendencies to certain maladies is especially desired.

H. A. S., M.D., Pittsburgh.

THE COEFFICIENT OF ROBUSTNESS

To the Editor:—What rule is to be applied to secure the coefficient of robustness?
H. Aveso y O'Horne, M.D., Merida, Mexico.

ANSWER.—Pignet, a French military surgeon, in the course of certain anthropologic studies on soldiers evolved an empirical standard of physical fitness or so-called coefficient of robustness which has been used to a great extent in Europe, especially for the purpose of determining the physique of soldiers. His formula is: $F = H - (C + W)$. H is height in centimeters, C the chest measurement in centimeters at greatest expiration, and W weight in kilograms. The larger the factor, the poorer the physique. When F is less than 10, a person is very strong; between 10 and 15, strong; between 15 and 20, good; 20 and 25, medium; 25 and 30, weak; above 30, very weak. In rare cases, F becomes negative.

An attempt was made by Capt. J. A. Black of the Royal Army Medical Corps to adapt Pignet's formula to English measurements with the following results: $F = (H' + C) - W$. H' is weight in pounds, C the chest measurement in inches at full inspiration, and W the height in inches. When F is over 120 a man is classed as very strong; between 110 and 120, strong; between 100 and 110, good; between 90 and 100, fair; between 80 and 90, weak; under 80, very weak.

Pignet's formula can, of course, serve as a basis of comparison, but it is far from being a definite standard.

ELIMINATION OF ANTS

To the Editor:—In *THE JOURNAL*, Aug. 2, 1919, Dr. Brandon of Essex, Mo., asks for an efficient device for the eradication of ants. Two years ago we conquered an invasion of ants, but found the "antiseptic brain of the ant" for the time being fully as intelligent as Sir John Lubbock claimed in his interesting account of them. The successful repulsion of these Huns was not effected until we employed lime, whitewashing profusely and completely the walls, steps and sills where ingress could be made. The cellar floor was also liberally whitewashed, and food placed in uncontaminated receptacles on the white-washed floor temporarily until the insects could be given a bath of whitewash wherever they had been. We have had no trouble since, as we repeat the external whitewashing every spring, and they no longer pass, they have evidently met their Vermin.

H. P. ASHE, M.D., Pittsburgh.

Per Capita Cost of Insanity.—The total cost of maintenance of insane patients in the state hospitals in the fiscal year 1917 was \$43,926,888.88. The average per capita cost based on the average daily patient population was \$207.28. The highest per capita cost, \$306.97, was reported by the state of Maine; the lowest, \$135.90 by the state of Virginia.—*State Hospital Quarterly*, Utica, N. Y., May, 1919.

Idaho April Examination

Hon. Robert O. Jones, commissioner of the Idaho Department of Law Enforcement, reports the written examination held at Boise, April 1-2, 1919. The examination covered 11 subjects and included 110 questions. An average of 75 per cent. was required to pass. Eleven candidates were examined, all of whom passed. Twelve candidates were licensed through reciprocity. The following colleges were represented:

College	PASSED	Year Grad.	Pct. Cor.
Chicago Hospital College of Medicine	(1918)	77
Heriott Medical College, Chicago	(1901)	78
Loyola University, Chicago	(1918)	77
Rush Medical College	(1880-'75, 1914-'78, 1917)	80, 83
St. Louis College of Medicine, Louisville	(1897)	75
Medical School of Maine	(1897)	75
Reelected Medical University, Kansas City, Mo.	(1914)	80
University of Cincinnati	(1916)	79

College	THROUGH RECIPROcity	Year Grad.	Reciprocity with
College of Medical Examiners	(1917)	Washington
Harvard University	(1917)	California
Denver and Gross College of Medicine	(1905)	Utah
Rush Medical College	(1903)	Washington, 1914
Rocky Mountain College	(1905)	Washington
University of Louisville	(1905)	Arizona
University of Oregon	(1905)	Washington
University of Oregon	(1918)	Washington, 1918, 21
Jefferson Medical College	(1891)	Utah

Utah April Examination

Dr. G. F. Harding, Secretary of the Utah State Board of Medical Examiners, reports the written examination held at Salt Lake City, April 7-8, 1919. The examination covered 19 subjects and included 100 questions. An average of 75 per cent. was required to pass. Six candidates were examined, all of whom passed. Four candidates were licensed through reciprocity. The following colleges were represented:

College	PASSED	Year Grad.	Pct. Cor.
Rush Medical College	(1918)	87.17
Harvard University	(1916)	85.5
University of Nebraska	(1919)	84.5
Columbia University, College of Phys. & Surg.	(1918)	81.7, 84.4

College	LICENSED THROUGH RECIPROCITY	Year Grad.	Reciprocity with
Chicago Medical College	(1890)	Iowa
Marion Sims College of Medicine	(1899)	Colorado
University of Tennessee	(1882)	S. Carolina
National University, Athens	(1897)	Illinois

* Granted M.B. Degree in 1918 after completing four year course; will receive M.D. after completing his intern year.

Arkansas May Examination

Dr. T. J. Stout, secretary of the Arkansas State Board of Medical Examiners, reports the written examination held at Little Rock, May 2, 1919. The examination covered 12 subjects and included 120 questions. An average of 75 per cent. was required to pass. Of the 33 candidates examined, 30 passed and 3 failed. Eighteen candidates were licensed through reciprocity. The following colleges were represented:

College	PASSED	Year Grad.	Per Cent.
College of Phys. and Surgs., Little Rock	(1910)	76.6
Indiana University	(1896)	82.6
University of Arkansas (1904) 85.1, (1906) 82.1, 82.7, (1908) 84, (1910) 84.8, (1919) 83.4, 84, 84.5, 85.2, 89.1, 92.4	84.5
Hospital College of Med., Louisville	(1903)	89.4
Tulane University	(1903) 82.4, (1910) 82.4	79.5
University of Maryland	(1917)	75.1
Hennepin University	(1897)	92
Cornell University	(1906)	85.7
McHARRY Medical College (1919) 75.6, 79.1, 80.4	(1908)	85.5, (1910) 82.5, 83.5, 90.5, 90.6, 91
University of Tennessee, College of Medicine (1918) 85.5, (1919) 82.5, 83.5, 90.5, 90.6, 91	(1918)	82
Vanderbilt University	(1918)	70.1
University of Arkansas	(1918)	68.3
McHARRY Medical College	(1918)	70.8

Vanderbilt Univ. (1892) Oklahoma, (1896) Texas, (1917) Tennessee	(1917)	Tennessee

Hawaii May Examination

Dr. J. R. Judd, secretary of the Hawaii Board of Medical Examiners, reports the written examination held at Honolulu, May 5-8, 1919. The examination covered 8 subjects and included 64 questions. An average of 75 per cent. was required to pass. Of the 5 candidates examined, 2 passed and 3 failed. The following colleges were represented:

College	PASSED	Year Grad.	Per Cent.
University of Illinois	(1914)	80.4
Tulane University	(1910)	79.7
University of Louisville	(1910)	73.4
Los Angeles School of Medicine	(1917)	74
Tokyo Imperial University	(1916)	61.6

Nevada May Examination

Dr. S. L. Lee, secretary of the Nevada State Board of Medical Examiners, reports the written examination held at Carson City, May 5-7, 1919. The examination covered 13 subjects and included 100 questions. An average of 75 per cent. was required to pass. Eight candidates were examined and passed. Four candidates were licensed through reciprocity. The following colleges were represented:

College	PASSED	Year Grad.	Per Cent.
College of Medicine, Practitioners	(1912)	91
Boston University	(1917)	85
Kansas City University of Physicians and Surgeons	(1910)	81.5
California University, College of Physicians and Surgeons	(1905)	81.6
University of Illinois	(1912)	83.7
Jefferson Medical College	(1916)	85.1
Tulane University, School of Medicine	(1907)	81.9
Trenton Medical College	(1888)	81.9

College	LICENSED THROUGH RECIPROCITY	Year Grad.	Reciprocity with
University of California, College of Medicine and Surgery	(1914)	Arkansas
University of California, College of Medicine	(1906)	Illinois

Allama Medical College	(1909)	Illinois

Book Notices

THE ELEMENTARY NERVOUS SYSTEM. By G. H. Parker, Sc. D., Professor of Zoology, Harvard University. Cloth. Price, \$2.50 net. Pp. 229, with 53 illustrations. Philadelphia: J. B. Lippincott Company, 1919.

This volume, the second of a series of monographs on experimental biology by American investigators, includes an "extended discussion of only the simplest examples of the elementary nervous system" as Parker himself states in the opening sentence of the last chapter. The author shows that contractile tissue (as effectors in the form of muscle cells) appears before any form of nervous tissue. Subsequently, there is added a receptor or modified epithelial cell which influences the effector more quickly because it is more sensitive to the external stimuli (chiefly physical) which originally acted on the effector organ directly. It is a "trigger," so to speak, to discharge the underlying muscle, and judging from the quickness with which this discharge is accomplished as compared with that with which the independent effectors discharge, the efficiency of the new system is beyond doubt." To this receptor-effector system is added later on a third type of cell, situated between the receptor and effector, designated by Parker the protoneuron, the ancestor of the neuron of more complex types of animals. The nerve net is thus evolved. The migration inward of this nerve net with its diffuse transmission of impulses leads to the beginning of the adjuster organ (central nervous system) in that the transmitting fibers arrange themselves into tracts showing physiologic polarity of conduction. The protoneurons of the nerve net evolve into the neurons of the nervous system. The first and last chapters of the book outline admirably the author's conceptions and the morphologic and physiologic data which lend support to these views. The remaining twelve chapters present the evidence in great detail as obtained from anatomic studies and physiologic experiment from various types of invertebrates (sponges, coelenterates and ctenophores). Most readers, except specialists, will no doubt judge that the contents could have been incorporated in a volume half its size. This is due in great part to the development of the theme along historical lines. The most interesting example of the latter is the delightful account of the development of our knowledge concerning the structure of nerve, nerve cells and nerve nets (Chapter IX). The book is written in an admirable style.

THE NEW PHYSIOLOGY AND OTHER ADDRESSES. By J. S. Haldane, M.D., LL.D., F.R.S. Cloth. Price, \$2.75 net. Pp. 156. Philadelphia: J. B. Lippincott Company, 1919.

The six addresses discuss biologic knowledge in relation to other departments of knowledge. The main point emphasized and developed from various points of view is that biology is an independent science and not merely applied physics and chemistry. The titles of the addresses are: "The Relation of Physiology to Physics and Chemistry"; "The Place of Biology in Human Knowledge and Endeavor"; "The New Physiology"; "The Relation of Physiology to Medicine"; "The Theory of the Development by Natural Selection"; and "Are Physical, Biological, and Psychological Categories Irreducible?" In the first address the main contention is that "in physiology, and biology generally, we are dealing with phenomena which, so far as our present knowledge goes, not only differ in complexity, but differ in kind from physical and chemical phenomena; and that the fundamental working hypothesis of physiology must differ correspondingly from those of physics and chemistry." In the second address it is pointed out that the hypothesis that living organisms exist as such, and that their structure and activities are the expression of their existence, has the same defects as other working hypotheses, but that it is necessary for the biologist, though inconsistent with physicochemical conception of the universe. The third address centers around the claim that the attempts to analyze living organisms into physical and chemical mechanisms is a colossal failure and concludes with an interesting statement of the relations of practical medicine to biology as distinguished from mechanistic physiology. In the fourth address the relation of

physiology to medicine is discussed more fully, and stress is laid on the great need at present for basing the study of anatomy, physiology, pathology and pharmacology on "the distinctively biological conception of organic regulation." In the two remaining addresses the inadequacy of mechanistic explanations of life and its activities is canvassed with special reference to natural selection and psychology. The addresses are interesting and animating, and should be read widely by physicians because they tend to broaden the point of view and to prevent empiricism and stagnation.

THE ANATOMY OF THE PERIPHERAL NERVES. By A. Melville Paterson, M.D., F.R.C.S., Lieut. Colonel R. A. M. C., Assistant Inspector of Special Military Surgical Hospitals. Cloth. Price, \$4.50. Pp. 165, with 64 illustrations. New York: Oxford University Press, 1919.

The percentage of peripheral nerve lesions among the casualties of the late war was so high that brief accounts of the anatomy, physiology and pathology of peripheral nerves fill a very important part in the present literature. In this book the author presents briefly the anatomy of the peripheral nerves for the use of students and surgeons, particularly for those engaged in military orthopedic work. The contents of the book consist of chapters on the anatomy of the peripheral nerves, the distribution of the spinal nerves, the sympathetic system, and the cranial nerves. It would have been better if some of the views of the author relative to regeneration and degeneration of nerves, in view of their unsettled nature, had been omitted from the text. It is by no means established that living fibers are found in the distal as well as the proximal portion of a divided nerve, and that new growing axons are derived from both of these portions. The author's statement relative to restoration of function following a section of a nerve and its immediate suture cannot withstand a critical analysis. Communications between the various nerves are described in a manner which permits one to understand the retention of power ordinarily supposed to be lost following the interruption of a particular nerve. As the book was intended primarily for surgeons in the military service, it would perhaps have added to its value to include in the description of the cranial nerves their relation to each other at the base of the skull. The original illustrations are very good, but the reproductions of illustrations from other sources could be improved. In general, the volume is a useful one to the readers for whom it was intended.

HEALTH EDUCATION IN RURAL SCHOOLS. By J. Mace Andrews, Ph.D., Head of the Department of Psychology and Child Study, Boston Normal School. Cloth. Price, \$1.60. Pp. 321, with illustrations. Boston: Houghton, Mifflin Company, 1919.

This book is intended primarily for teachers in rural schools, with a view to aiding them to present to their classes the elements of hygiene. The author, we are informed, was born in the country, attended rural schools, taught in rural schools, served as a member of the county board, and has been for several years an instructor in hygiene and child study in normal schools. With this excellent equipment he has prepared a book which is well worth while. It presents the elements of the subject in simple language, and follows each chapter with suggestive class exercises and a list of bibliographic references, which will enable those wishing further knowledge to find it. It is to be hoped that those interested in the administration of our rural schools will avail themselves of the opportunity offered them to improve hygiene and hygienic instruction through the use of this textbook.

CHEERIO! By Harold M. Hays, Major, M. C., U. S. A. Cloth. Price, \$1.50 net. Pp. 251. New York: Alfred A. Knopf, 1919.

The war resulted in a flood of books relative to the experiences of men in the various services. Some half dozen books of medical experiences have already been noted in this department. All are of interest as showing the particular point of view of the authors. All have been marked by the cheerfulness with which the officers viewed the many hardships of their service. Major Hays' book reflects a cheerful disposition under adverse circumstances. He and his unit seem to have been looking for the brighter side of things. The book is a pleasantly reminiscent one.

Medicolegal

Mental Capacity Required to Transact Business

(*Sutcliffe v. Heatley (Mass.)*, 122 N. E. R. 317)

The Supreme Judicial Court of Massachusetts holds that a note and mortgage were void when they were signed by a woman who had been subject to epileptic fits for about ten years and her mind had become permanently impaired and she did not have sufficient mental strength to care properly for her property and to understand the effect of the mortgage and note, and derived no benefit from signing them, the entire proceeds going directly to her brother, through whose undue influence she was induced to sign them, though she had sufficient capacity to understand that she was signing a note and mortgage, and did so understand, but was not of sufficient capacity to realize the effect it might have on her estate and to judge of the wisdom or unwisdom of the transaction. The court says that the test in cases of this kind is whether the person executing the instrument had sufficient mental capacity to be capable of transacting the business. If she could not understand the nature and quality of the transaction or grasp its significance, then it was not the act of a person of sound mind. There may be intellectual weakness not amounting to lack of power to comprehend. But an inability to realize the true purport of the matter in hand is equivalent to mental incapacity. When this is established, then a contract is voidable. It is no defense that the other party acted fairly and without knowledge of the want of mental faculty or of any circumstances which ought to have put him on inquiry. This case came within this rule.

Misrepresentations by Applicants for Insurance

(*Myers v. Mutual Life Ins. Co. of New York (W. Va.)*, 98 S. E. R. 424)

The Supreme Court of Appeals of West Virginia, which distinguishes between representations and warranties, holds that, in determining whether or not an applicant for insurance has been treated by a physician so as to render voidable a policy of insurance issued to him on the representation that he has not been so treated, prescriptions for slight temporary ailments will not be considered; neither will such slight temporary ailments be taken into consideration in determining the truth or falsity of a representation as to diseases or maladies with which the insured may have been afflicted. But a policy of insurance, issued on an application therefor, in which the representation is made, in answer to a question asked, that the insured had not consulted or been treated by a physician within five years next preceding the making of the application, will be avoided at the instance of the insurer on a showing that the insured within that time had been treated for several consecutive months for a chronic malady with which he was then suffering. A policy of insurance will also be avoided at the instance of the insurer, when the insured, in answer to a question in his application for insurance, states that he has since childhood suffered only from certain named complaints, from which he has fully recovered, when the evidence shows that he was treated for several months at a long time subsequent to the complaints mentioned by him for a disease with which he was then suffering.

Correct Practice Relative to Expert Testimony

(*Commonwealth v. Ross (Mass.)*, 122 N. E. R. 176)

The Supreme Judicial Court of Massachusetts, in holding that, in this case, wherein it was an issue at the trial whether the death of the defendant's wife was due to strangulation or to hemorrhage, it was a subject about which expert testimony was competent, says that the correct practice as to the introduction of such testimony is well settled. The competency of an expert witness to testify by his opinion rests on unusual knowledge and extraordinary experience, superior to that of ordinary persons. The witness, being qualified in this particular, then may base his opinion on facts observed by himself or within his own knowledge and testified to by

himself, or on facts assumed in the questions put to him and supported either by admitted facts or by the testimony of other witnesses already given or to be given at the trial, or on facts derived partly from one source and partly from the other. It is not necessary in all cases that the facts be stated in the form of a hypothetical question, although this is generally permissible. When an opinion is sought on substantially uncontradicted testimony heard by the witness with or without personal observation on his part, the question may be asked on that express or implied assumption without reciting the testimony in the question.

When there is conflicting testimony, a witness, who has been present in court and heard it, may be asked if he has formed an opinion as to a material point, respecting which his skill gives him requisite qualification to express an opinion, based on that testimony or parts of it. If his answer is in the affirmative, then he may select and state the facts given in testimony which in his opinion, if true, are most significant and pertinent as aids in the formation of an opinion and to what conclusion his mind is led by the consideration of such facts.

In the trial of a criminal or other case, it is permissible to ask an expert witness if he has formed an opinion from his observations and examination and from testimony heard in court as to the point in issue about which he is qualified to give evidence. On answering in the affirmative he may be asked to state that opinion. The direct examination then may stop, leaving the other side to develop the reasons in whatever detail may be desired. The forms of question given in decided cases may not be exclusive of all others.

It is essential, however, that in giving testimony the expert witness should not undertake to pass on the truth of the fundamental hypothesis on which his opinion rests unless it is within his own observation and knowledge. He simply must assume those facts as the basis of his opinion. It is the province of the jury alone to decide whether those facts are established. If they are established in substance to the satisfaction of the jury, then and not until then can the value of the expert evidence be taken up by them. If such facts are not so established, then the jury does not reach at all the consideration of the expert testimony.

Manifestly an opinion not grounded either on facts observed by the witness or on facts assumed and specified in the question or on facts in evidence through other witnesses, but based on facts taken on the hearsay of others out of court and not in evidence and not put in the form of a supposition in the question, is not admissible in evidence. Such an opinion would or might well be founded on facts, the truth of which could not in the nature of things be established to the satisfaction of the jury because no competent evidence respecting them would be before the jury.

As to the order of introduction of evidence and the form of questions, much must be left to the discretion of the presiding judge.

An expert witness cannot fortify his opinion by putting in evidence incompetent facts.

Liability of Husband for Medical Services to Wife

(*Ward v. Johnson (Ga.)*, 98 S. E. R. 405)

The Court of Appeals of Georgia, Division No. 2, in reversing a judgment of nonsuit, holds that, on the trial of a suit against a husband for medical services rendered by the plaintiff to the defendant's wife, evidence that before the date of the rendition of the services by the plaintiff, the defendant left the state as a fugitive from justice, carried his wife with him, and that she later returned to the former community and lived on land belonging to the husband, the husband still remaining away, does not necessarily demand the inference that the parties were living in a state of separation as husband and wife under such circumstances that the husband would not be liable for necessities, such as medical services furnished by the plaintiff to the wife. Whether credit was extended to the husband or to the wife, and whether the parties were living in a state of separation as husband and wife and under such circumstances as would make him liable for necessities furnished her, were questions for the jury.

AMERICAN SOCIETY FOR CLINICAL INVESTIGATION

Annual Meeting held in Atlantic City, N. J., June 14, 1919

(Continued from page 639)

Blood Examinations of Trinitrotoluene Workers

DR. GEORGE R. MINOT, Boston: Two hundred and thirty-three essentially unselected individuals were studied. Red cell abnormalities were found to be very frequent. The most interesting abnormality was the frequent finding of fragmented or fragmenting red cells which have a definite histologic character. These cells appear to afford evidence of a rapid increased destruction of the red cells. Evidence shows that distinct increases of these cells are to be looked on as a significant sign of a considerable degree of poisoning; and probably when they occur in large numbers, they indicate some degree of toxic jaundice. Among other red cell abnormalities noted were the following: Polychromatophilia occurred in 83 per cent. of the cases, often to a marked degree. Howell-Jolly bodies, stippling and blasts were found, and increased numbers of reticulated red cells. The red cell count averaged in the mildest cases 4,500,000, and in the severest 3,800,000. It was found that there was usually a definite relationship between the total amount of red cell changes and the symptoms. Methemoglobin or some form of changed hemoglobin is apparent in these cases.

The white blood cells do not furnish as much information concerning the worker's condition as do the red cells. Slightly increased white cell counts were common. The observations showed that an individual may become distinctly and severely poisoned with a normal, or an absolute or relative increased, lymphocyte count, or with an increased or normal polymorphonuclear count. However lymphocytosis is to be looked on as an undesirable sign, but does not necessarily indicate that significant poisoning will occur or is occurring, except when there is a leukopenia. Slight eosinophilia (more than 5 per cent.) occurred in 10 per cent. of the cases. It was more common in cases with slight symptoms than in those with marked.

The blood platelets were usually slightly increased. Their diminution was observed twice and in both cases there was a relative lymphocytosis. Such a condition should certainly be regarded as evidence of a severe effect on the marrow, indicating aplasia. Webster's test for changed trinitrotoluene in the urine was found to be less valuable than blood examination to indicate the worker's condition.

Value of Urobilin and Urobilinogen of Stool and Urine in Diagnosis and Prognosis of Pernicious Anemia

Drs. G. H. HANSMANN and C. P. HOWARD, Iowa City: Our material consisted of twenty-seven cases of pernicious anemia and nine miscellaneous conditions. The method used was a modification of the Wilbur and Addis spectroscopic method described by J. D. Boyd. The evidence of abnormal hemolysis occurs first in the stools, secondly in the duodenal contents, and lastly in the urine. An increase of the urobilin and urobilinogen in the urine and stools above 12,000 dilutions is a constant finding in pernicious anemia during the period of remission. The presence of even small amounts of

urobilinogen in the urine is evidence of a probable pernicious anemia in the absence of signs of biliary or hepatic disease.

A low red cell count with a low urobilin and urobilinogen content indicates an arrest of the activity of the disease process, and that a period of improvement may be anticipated. On the other hand, a high red cell count with a high urobilin-urobilinogen content indicates a marked hemolysis and often precedes a steadily falling blood count, as was also demonstrated by McCrudden.

Active Immunity Against Experimental Pneumococcus Pneumonia

DRS. RUSSELL L. CECIL and FRANCIS G. BLAKE, Washington, D. C.: The production experimentally of typical lobar pneumonia in monkeys affords an ideal method of testing the value of various pneumococcus vaccines. The injection of killed cultures of pneumococcus into ordinary laboratory animals will protect them against lethal doses of virulent pneumococci injected intravenously; but this is not equivalent to preventing the disease itself. An equally efficient immunity exists in monkeys following an attack of experimental pneumococcus pneumonia. This immunity appears to be similar in all respects to that following vaccination with a living culture. It has been found possible to produce lobar pneumonia in monkeys by the intratracheal inoculation of minute amounts of pneumococcus culture. The disease produced is entirely comparable to lobar pneumonia as seen in man both in its clinical and in its pathologic features. The opportunity presented to study the histogenesis of lobar pneumonia from the earliest stages of invasion of the lung by the pneumococcus to beginning resolution has brought out some interesting facts. The pneumococci primarily penetrate the mucous membrane of the larger bronchi near the central portion of the lung and there set up an inflammation of the perivascular and peribronchial tissue as shown by infiltration with polymorphonuclear leukocytes and edema. The process advances by direct extension to the adjacent alveolar walls and by way of the lymphatics toward the periphery of the lung, being at first entirely interstitial in character before actual exudation into the alveolar spaces has occurred. Consolidation subsequently occurs by the pouring out of the exudate into the alveolar spaces, at first serous and then cellular, until complete hepatization of one or more lobes has occurred.

DISCUSSION

DR. FRANCIS G. BLAKE, Washington, D. C.: The perivascular infiltration and interstitial character of the process in the early stages of lobar pneumonia as seen in monkeys, either killed or dying soon after inoculation, is not commonly seen in man because men do not die sufficiently early in the disease for this feature of the pathologic condition to be at all prominent. It is in many respects comparable to the early stages of pneumococcus pneumonia following influenza except so far as the picture has been modified by the preceding or concomitant influenza infection.

DR. S. J. MELTZER, New York: In the course of last winter, Wollstein and I again carried out a large series of experiments in the production of pneumonia in dogs by the method of insufflation. The insufflated dogs either died within twenty-four hours or after from six to ten days with characteristic clinical symptoms. Some dogs temporarily recovered from the disease to die or to be killed later. The pathologic pictures revealed at the various necropsies manifold lesions, depending on the degree of the virulence of the culture, on the quantity insufflated, and on the time of the year when the experiment was conducted.

Bone Marrow Changes in Mustard Gas Poisoning

DR. E. B. KRUMBHAAR, Philadelphia: When yellow cross gas (mustard gas) was first used against the Allies in July, 1917, we found that an extraordinary leukopenia developed in the severe cases, often reaching less than 1,000 cells per cubic millimeter. This leukopenia (chiefly due to diminution in the polymorphonuclears and disappearance of eosinophils) followed an initial leukocytosis and reached its climax during the second week after gassing, at the time when the mortality curve was highest. It was therefore

thought that the lack of leukocytes in the circulating blood might have an important bearing on the lack of resistance to secondary infections that was shown by such cases. A study of the bone marrow in fifty-five fatal cases showed an inhibition of the blood regenerative process, which, as it occurred both in the absence of infection and in the presence of pyogenic infection, was taken to be due to a directly toxic action of the poison on the bone marrow. Fourteen marrows showed an almost complete aplasia, and twenty-eight a very slight and thirteen a moderate hyperplasia, but in none was hematopoiesis as active as in marrows from such acute infections as pneumonia, meningitis, typhoid and influenza. The cellular constituents of the hematopoietic areas also emphasized the inadequacy of the attempts at regeneration. Immature forms were most prominent, together with fair numbers of phagocytes and pigment indicators of increased blood destruction. Blast forms were uncommon, but polymorphonuclears were even rarer, and in some cases almost entirely absent. In the case of those patients who died after the second week, when leukopenia no longer existed, hyperplasia of the marrow was more marked, and polymorphonuclears and normoblasts were more in evidence.

ASSOCIATION OF AMERICAN PHYSICIANS

Thirty-Fourth Annual Meeting, held at Atlantic City, N. J.,
June 16-18, 1919

(Concluded from page 637)

Experiments with Cultures of Streptococci, with Special Reference to Empyema

DR. F. P. GAY, Berkeley, Calif.: I succeeded in producing empyema in the rabbit by injection of a streptococcus culture into the pleural cavity; I have not succeeded in producing empyema by introduction through the respiratory tract. The cultures which will produce empyema will not produce septicaemia; the organisms remain in the circulation for three or four days, but the animal does not die. The culture will not produce peritonitis. Vaccines such as are used in the vaccination of human beings have had no effect in preventing this empyema. Experimental animals are rendered more susceptible, except in cases of long continued inoculation for six weeks or more, when it becomes immune; but no serum or vaccine capable of curing the animal of empyema has been obtained.

New Method for Testing Immunity by Means of the Whole Blood, with Especial Reference to Pneumonia and Its Prophylaxis by Bacterination

DRS. S. S. COHEN and G. H. HEIST, Philadelphia: We wished to know whether certain drugs modified the development of the disease; also, whether the existence of natural or artificial immunity in men or animals can be demonstrated by a better or simpler method than agglutination, and whether the existence of protective substances in the blood, or recovery without their development, can be demonstrated after certain prophylactic or therapeutic measures. The results with serum, defibrinated blood and citrated blood were inconsistent and contradictory. Remembering an observation of Wright's which, however, he had not published, namely, that the whole blood of immunized animals, as it flowed from the vein, killed pneumococci, we tried to develop a simple and workable way of testing this germicidal power of the whole, unaltered, flowing blood, in which only a small quantity of blood need be used, and the manipulations can be completed before coagulation began. The solution of the problem came from Prof. E. F. Lacy, of the department of physics of the Central High School of Philadelphia, and the technic was worked out by Dr. Heist. It is therefore termed the "Lacy-Heist" method. A capillary glass tube is filled up to a mark with broth culture of pneumococci and then emptied of fluid by touching its tip to a piece of moist gauze. A film containing a certain number of pneumococci remains sticking to the wall of the tube. Blood as it came from the capillary or vein was allowed to flow up the seeded tube to

the mark; and it was then sealed and incubated for twenty-four hours at 37 C., when a drop was blown on a slide and stained. By using a multiple fan shaped pipet, such as Wright used for coagulation, several dilutions of the culture in multiples of five or ten might be used and an approximately quantitative result obtained. If the blood had no bactericidal action, the pneumococci multiplied freely. If it was bactericidal, they were killed and no growth resulted. The reaction was sharp—either there was abundant growth, or the bacteria were killed, as shown by the absence of colonies on centrifugation and plating. This test gave constant results. Pigeons are naturally immune to pneumococcal infections. Their blood destroyed virulent cultures that flourished in mouse and rabbit blood. On the other hand, the blood of mice and rabbits suitably immunized destroyed the cultures. No bacterial action resulted from the serum of the defibrinated blood either of the naturally immune pigeon or the inoculated rabbit. Similar observations were made on human blood, showing some men to be naturally immune, others to be susceptible, and others to have acquired immunity by inoculation or by recovery from pneumonia. Cultures that failed to grow in immunized rabbits' blood proved to have lost their virulence. The animals survived large doses. When the virulence was restored by passage through mice and rabbits, the bacteria grew in the capillary tubes. The living culture killed the animal. Such cultures were used as tests for immunity. After inoculation with killed pneumococci by a special method of preparing the vaccine, Dr. Heist was able to produce immunity to Type III as well as to Types I and II and to demonstrate this immunity by the method here described. Even when agglutination tests failed or as in Type III were inapplicable, tests were made with other organisms, pathogenic and nonpathogenic, including *B. subtilis*, meningococci, and the globoid bodies of poliomyelitis. We concluded from these uniform results that bacteria which would not grow in the whole blood of an animal or man were nonpathogenic for that species or individual, while those that did so grow were pathogenic. We concluded, likewise, that in both natural and artificial immunity there is in the whole blood a protective force or quality not to be found in any fraction of it. We do not know what this is, nor do we know that it is the same in the two instances. Very probably it is not.

Rapidity and Persistence of Action of Digitalis on the Heart

DR. G. CANBY ROBINSON, St. Louis: A study of digitalis was made on patients suffering from a form of cardiac disorder which is so influenced by digitalis that it could be determined definitely when the drug begins to take effect, and in most cases when its action ceases. Digitalis was usually administered in one large dose in the form of the tincture which had been assayed by the cat method of Hatcher and Brodie, and was given by mouth. The dose was determined by the method described by Egleston, and 0.15 c.c. was given per pound of body weight. In a few instances this dose was reduced on account of certain clinical findings. Twenty-six cases were studied and tabulated. The maximum effect of digitalis, as judged by the slowest ventricular rate, was usually observed in from fifteen to twenty-six hours. In thirteen cases the heart remained under the influence of digitalis from four to twenty-two days, or an average of nine days and eight hours. In one case the effect lasted only one day, while in the others no definite statement is justified, because subsequent doses of the drug were given before the effect of the first dose had disappeared or, as in one case, the patient died. The study of these cases demonstrates that a single large dose of the tincture of digitalis given by mouth affects the heart soon after administration, and at relatively uniform time, indicating that the drug is well absorbed, at a uniform rate. It also demonstrates that the maximum effect is usually obtained in about twenty-four hours and generally continues to be effective for nearly ten days.

Thrombosis of Coronary Arteries

DR. EMANUEL LIBMAN, New York: The term "angina pectoris" should be dropped and replaced by "cardiac pain."

The most common causes of pain in the cardiac area are: (1) hypertension with dilatation of the arch of the aorta with or without narrowing of the arch; (2) Hodgkin's disease; (3) syphilis of any part of the vascular system, and (4) disease of the coronary arteries. The usual sequence of events in cases of coronary thrombosis is, first, the closure of the artery; second, the infarction of the artery; and then a later period in which there is cardiac pain and, perhaps, rupture of the heart. Infarction can be diagnosed by the active pericarditis, but the infarction may be in the back of the heart. In thrombosis, a valuable sign is leukocytosis. A hint is given by feeling other arteries in the body; the patient may have had intermittent claudication. Search the history for evidence of ptomain poisoning, and whether after recovery the patient had difficulty in walking. Another symptom of thrombosis of the coronary arteries is a peculiar leaden tint, although not every patient develops this color. In thrombosis of the right coronary artery there is apt to be acute enlargement of the liver.

Early Diagnosis of Intestinal Tuberculosis

DRS. LAWRASON BROWN and H. L. SAMPSON, Saranac Lake, N. Y.: Ulcerative peritonitis is difficult to diagnose clinically. A patient with a lung lesion who complained of indigestion and constipation, with long persistent elevation of temperature, was found to have a tuberculous colitis. A study of the roentgenograms showed the barium located in the cecum. Of seven cases of ulcerative colitis examined, in six there was tuberculous colitis. The diagnosis was founded on hypermotility of the tract, as shown by the roentgen ray, and filling defects which were interpreted as spasm. One patient had tuberculosis of the hepatic flexure with a membrane at that point. Often it was noted that when the barium had been evacuated at the end of twenty-four hours, there remained an ileac stasis, in which the barium did not pass the ileocecal valve. In almost every case there was spasm of the cecum. Pain, nervous diarrhea, and gas are prominent symptoms in these cases, which are often difficult of diagnosis, but which may be benefited by operation.

A Case of Ayerza's Disease (Chronic Cyanosis, Chronic Dyspnea, Erythremia, Enlargement of the Liver and Spleen and Hyperplasia of Bone Marrow) Associated with Syphilitic Sclerosis of the Pulmonary Artery

DR. A. S. WARTHEIM, Ann Arbor, Mich.: This is a case of chronic cyanosis, dyspnea and erythremia, observed clinically over a space of five years. It was at first supposed to be one of mediastinal tumor, as the roentgen ray disclosed a large, well marked shadow above the heart. This did not increase in size. The patient was a laborer. He showed chronic cyanosis and polycythemia. The red blood count was from 7 to 8 million cells. Later the case was recognized as one of Osler-Vaquez disease. The clinical course was characterized by attacks of angina, hypercyanotia, cyanosis, increasing weakness, drowsiness, edema, asthma, dyspnea, enlargement of the spleen and liver, multiple telangiectasis, and constant erythremia. The man was fairly comfortable for some time but finally developed large spleen and liver, and very marked somnolence, which was in accord with the Spanish description of the disease.

At the postmortem examination the findings were: extreme atherosclerosis of the pulmonary artery and all its branches, extreme dilatation of the right heart, fibrosis and emphysema of the lungs, extreme angiectasia of the entire vascular system, enlargement of the liver and spleen, and hyperplasia of the bone marrow. The microscopic examination revealed the presence of a typical syphilitic mesarteritis of the pulmonary artery and aorta, chronic fibroid myocarditis, pancreatitis, orchitis, leptomenigitis, suppurative infiltration of plasma cells, and also changes in the stomach wall of a syphilitic character.

Cancer of Pancreas

DR. T. B. FETTER, Baltimore: Fifty-eight cases have been noted among 41,000 patients admitted at the Johns Hopkins Hospital. We studied thirty cases in which the diagnosis

was confirmed by exploratory operation or by necropsy. Twenty-one were in males, nine in females. Most of the patients were in the fifth decade of life. Pain was a prominent symptom in all but six cases, and was located in the upper section of the abdomen. Jaundice was the most constant symptom. This was progressive, persistent and intense. One patient was almost black and had the appearance of argyria. A palpable tumor was present in twelve cases, in the apex of the epigastrium; this did not descend on deep inspiration. A distended gallbladder seemed to be an important diagnostic physical sign, and was different from the blocking of the common duct by stone, which did not cause distention of the gallbladder. In nearly all cases there was enlargement of the liver due to jaundice, but this lacked the features of ordinary catarrhal jaundice. This was sometimes due to lack of function of the pancreas, and acholic stools were noted with excess of fat. Such stools were present in twenty-two out of thirty cases. In two there was actual fatty diarrhea with from twelve to fourteen large, fatty, white stools in twenty-four hours, due to the growth's shutting off the pancreatic ferment from the intestinal tract. Glycosuria was present in 10 per cent. of the cases. The tumor was usually situated at the head of the pancreas; one was in the body. Eight were primary cases; two were secondary to carcinoma of the stomach and gallbladder, respectively. These were adenocarcinomas. There was one case of hemangio-endothelioma.

A New Roentgen-Ray Sign of Perinephritic Abscess

DRS. H. M. FUSSELL and H. K. PANCOAST, Philadelphia: A wavy appearance of the diaphragm on fluoroscopic examination is a valuable diagnostic sign in early detection of perinephritic abscess.

AMERICAN ORTHOPEDIC ASSOCIATION

Thirty-Third Annual Meeting, Atlantic City, N. J., June 14-17, 1919

(Continued from page 658)

Operative Treatment of Paralytic Conditions of the Upper Extremity

DR. ARTHUR STEINLER, Iowa City: Essential requirements for function of the upper extremity are: active abduction, or apposition of abduction of shoulder; ability of flexion of elbow; ability of pronation of forearm; hyperextension of wrist, either active or passive; active flexion of the metacarpophalangeal joints; free play of the fingers and power of opposing the thumb to the fingers. In flail shoulder there does not seem to be any reliable method of tendon transplantation. The indication here seems to be arthrodesis; this need not be complete, however. The problem of flail elbow is difficult as the arthrodesis cannot be undertaken in children under 14 or 15 years of age. Even then it is doubtful. Operation consists in causing the flexors and extensors of the wrist to act as flexors of the elbow; but flexion is limited and is of use only when the muscles are not weakened. A plaster cast is used for two months, and then a splint with a stop lock for six months, not more than 90 degrees of extension being allowed. In drop hand and flail wrist, stabilization of the wrist is an advantageous procedure. The result of the operation is not a complete arthrodesis, but rather limited wrist motion, from 10 to 30 degrees of extension. Tendon transplantation is done in addition in several cases. The operation of flexorplasty is done with advantage in restoring opposition of the thumb and thus the function of the hand. This operation is often performed in addition to other work on the hand and forearm. Lack of extension of the thumb is corrected by the method of Mayer and Biesalski, by taking the extensor of the index finger as a check to the flexors of the thumb. For flexion of wrist in "main-en-griffe" flexorplasty is done in some cases, and the cock-up splint, of the kind devised by Sir Robert Jones, is used in other cases. Flexorplasty of the elbow combined with arthrodesis of the shoulder, gave better functional results than in cases in which arthrodesis of the shoulder was not done. If arthrodesis of the wrist had been carried out in connection with elbowplasty, the elbow results would have been better.

DISCUSSION

DR. CLARENCE L. STARR, Toronto: We are now studying results on from 450 to 500 cases of nerve suture, after nerve separation from scar, and are attempting to find out what we have succeeded in doing. The results are very interesting. Early cases were those of bullet wounds and machine gun wounds, which generally healed within two weeks, but left complete separation of the nerve. In these, operation was performed early, and these have formed a large percentage of complete recoveries and restoration. In other cases that were supposed to be septic and in which the patients were brought home for treatment from eighteen months or two years after the injury there has been a very small percentage of recovery, so that they are almost hopeless. One has to choose the best time to operate. Dr. Kidner said that a large percentage of these men would recover if left alone, but many of them will not come anywhere near approximation, even if left till the crack of doom. Tennell's sign is a good one, but it is not reliable. Operation should not be delayed when it is found that the muscle power is going down, as tested by faradic and galvanic stimulation. Operation done under these indications usually shows what is expected. I have never seen a satisfactory case of nerve bridging with ultimate recovery. One can get recovery in nerves with purely motor function like the musculospiral and the sciatic. It seems occasionally as if there were rotation of the nerve and that the axis cylinders find their way from motor areas to sensory areas. A piece of shrapnel may twist a nerve a number of times, and it is almost impossible to get approximation of the proper filers. Best recoveries have been seen in the sciatic, the median and the musculospiral. In the upper extremity one has a good substitute in muscle transplantation, particularly in the musculospiral, in which one only has to overcome gravity. There is almost enough power to use the flexor tendons of the forearm and thumb, the wrist next and the fingers last. With a musculospiral injury one can transplant muscles and make a useful hand. The pronator radii teres can be taken from its insertion and inserted into the wrist, the pollicis longus can be transferred to the flexor of the thumb, the flexor carpi radialis to the extensors of the fingers. Tendon transplantation has been so satisfactory that one does not feel bad if the musculospiral is separated.

DR. CHARLES BAGLEY, JR., Baltimore: Considerable experience is necessary before one can interpret the action of the muscles. Often there is simulated action. The time element does not need consideration, but all cases without improvement need operation. The Tennell sign is merely additional evidence; one cannot depend greatly on it. Operation is not done till the wound is healed completely, and sometimes, while one is waiting for operation, the nerve has started to regenerate. After liberation of the nerve, and no sign of return of function, or in cases in which the nerve is tied up with scar tissue, or perhaps neuroma, it is better to do an end to end suture. Sometimes too much tension makes reoperation necessary. If nerve suture is done under favorable conditions, reoperation is not justified. The ideal time for operation would be when the wound had just healed. In cases in which circulation has been much interfered with, on account of extensive *debridement*, one is puzzled as to whether or not to free the nerve from scars, as this might interfere still further with circulation and make amputation necessary.

DR. SIBNEY M. COLE, Baltimore: Some things have perhaps been said too emphatically, for instance, Starr's statement that one cannot have a graft of nerve toward the periphery, when there is a large gap, as there is no connecting link between the two. There is much good clinical and laboratory work which refutes that statement. I believe that there are other methods of nerve growth than those actually seen, that is, from the central end. Even the most hopeful workers in clinical and laboratory study cannot say definitely whether growth is continuous or whether it takes place by effusion. I have no doubt that the proximal end, surrounded by Schwann's sheath cells, has a better chance to grow. I think also that nerve formation may take place in the distal ends of the scar formation of Dejerine. There is good reason

son why there should be more growth from the proximal end than from the trophic center. How, then, does the nerve find its way to the periphery? There are a number of questions in diagnosis, such as the character of the wound, the character of the muscle, the duration of the wound, the health of the individual, the time of year, the position of the patient when struck, nerve growth, and protein changes in the wound. The physiology of scar formation has to be considered, and infections of various kinds, the degrees of which have not been well studied. Probably nerves caught in a cellular embryonic state may produce growth which stimulates growth by first intention. Growth under pathologic conditions may be a different question. Often nerves have been seen showing wild growth through the sheath after operation. Scar tissue, however, prevents this. Even with foreign bodies, symmetrical nerve bulbs are seen, growing quite close up to the foreign body. There is also the question of the blood supply to the nerve. In cases in which the musculospiral and ulnar nerves have been completely separated for months, the amputated arm was studied, and a suggestion of growth of new nerve was found down to the wrist, not complete, but a suggestion of an attempt to form new nerve all the way along and some adult nerve with funnels.

Dr. ERNEST C. KIDDER, Detroit: The operative side of nerve surgery has been condemned unnecessarily. It is not necessary to wait long periods of time before operating on nerves. Usually it is safe to operate early by a two-stage method. One can go in within from two to three weeks after the skin has closed and find out what the condition is surrounding the nerves. Then one can close up and watch for sepsis, and if none appears, finish the operation. That will save the patient from six to nine months of waiting. The preliminary operation does not do any harm. Badly damaged nerves do not need operative interference except removal of bands of scar tissue. Badly chewed up nerves recover surprisingly well. For severed nerves, the earlier suture is done the better the prognosis. It is almost impossible to tell whether the nerve is severed or not. By waiting to find out, time is wasted. The simpler the operation the better. One sometimes finds cases of interposed foreign body, muscle or membrane actually preventing the union of nerve. This should be removed, and the ends brought together in an easy position with the finest silk suture. It is then replaced in the best bed it is possible to find, with relaxation of the suture line by the joints in the neighborhood. It is better to wait for nerve recovery rather than do tendon transplantation. This gives good results, or four or five months, then stretches, and leaves the patient unimproved. In injuries of the musculospiral, the hand adapts itself and becomes a useful hand, so that it hardly seems necessary to perform complicated and difficult operations. When one is in doubt about division of the nerve, it is useless to wait and prove the interruption; it is better to operate as soon as active sepsis has ceased. If there is any fibrous continuity whatever, one should wait two or three years; time and again such patients have recovered. If there is any fibrous continuity, the nerve would push through. Once an operation one can get a strong electrical response from tissue which looks like nothing but scar tissue, which proves that there are nerve fibers coming through. Even if there is no electrical reaction it is well to err on the safe side. In case of a gap in which end to end suture is impossible, one can perform a spinal connective and tie up the joint. Grafting is the last resort.

Dr. J. FORESTER REED, Philadelphia: Splints with pressure could be applied extremely carefully. The dorsum of the fingers will not stand pressure.

Dr. L. W. RYAN, Chicago: It is interesting to know whether any forms of filling in nerve gaps will succeed. Prof. Scott Hilder seems to think that planting the scuff of the calf will succeed in certain cases. Might it not be a good plan to adopt the policy of the French, and shorten the two bones of the forearm?

Dr. H. P. H. GAYLOR, Winnipeg, Man.: I can speak enthusiastically of tendon transplantation in those cases of musculospiral paralysis in which there is no hope whatever of restoring power to the muscles.

Circulatory Failure Due to Epinephrin.—The experiments reported by Erlanger and Gasser show that the injection of epinephrin for a period of from twenty to thirty minutes at such a rate as to maintain a high arterial pressure invariably constricts the arteries of both the somatic and the splanchnic areas. With large doses this constriction may be maximal and outlasts the injection period, it may be, for as long as two hours. This continued constriction is partly due to central action. After sufficiently large doses, the arterial pressure, barring occasional intercurrent phenomena, fall steadily and slowly until the animal dies. The jugular pressure, during or after large injections shows no constant alteration, at least not of a kind that indicates inefficiency of the heart. The heart may become irregular for a while and occasionally stop suddenly while the arterial pressure still is high. The respiration after large doses often is slowed and may suddenly or gradually fail. The portal pressure is increased, often markedly, during their injection, and may remain high subsequently; but not uncommonly it soon returns to the normal level. Evidence is presented indicating that accumulation of blood in the portal area as a result of the increased portal hepatic resistance is not in itself the cause of the failure of the circulation. The failure of the circulation is rather to be attributed to the extreme slowing of the blood flow throughout the body caused by the constricting action of the epinephrin of the arteries. It is concluded that the cause of the failure is the same as is operative after temporary partial obstruction of the vena cava or of the aorta.

Oxygen Consumption in Feeding and Starvation. The results of Hyman's observation on planaria are applicable to other organisms also. He found that starvation increases the metabolic rate of organisms, and that starved organisms are metabolically in a condition similar to that of young organisms.

Intraspinal Therapy in Neurosyphilis. Fordyce emphasizes again that the results following the treatment of syphilis are largely dependent on the age of the infection. For this

reason the importance of early diagnosis and energetic treatment has been emphasized. A serologic cure in cases of syphilis in the late secondary stage and following this is difficult to obtain and requires expert knowledge in the use of therapeutic agents. When the central nervous system is invaded the problem is complicated by the highly organized nature of the tissues, the results of secondary degenerations and the inaccessibility of the spirochetes in certain types of neurosyphilis. Success or failure in the use of intraspinal therapy depends on the technic employed and the persistence of the physician in carrying it out. Above all, it depends on the cytologic indications which are present in the spinal fluid for initiating or persisting in this mode of therapy. The order in which the various reactions disappear is indicated by Fordyce. The cytology is usually the first phase to be influenced in persistent infections. In some cases treatment must be continued for from one to two years before a definite impression is made on the globulin content or the Wassermann reaction. Modification in the intensity of the globulin reaction is usually followed by a weakening in the strength of the Wassermann reaction and by a change in the colloidal gold reaction. Rapid changes in the Wassermann reaction when strongly positive in the high dilutions, in Fordyce's experience, do not occur except in cases of early syphilitic meningitis. In old cases of neurosyphilis a gradual diminution in the intensity of the Wassermann reaction is of good prognostic import, and when it finally became negative Fordyce has reexamined patients after one, two, and three years who have shown no return of any of the previous phases.

Syphilis of Digestive Tract. Syphilis plays a very much more important role in gastro-intestinal pathology, according to Brown and Gaither, than is usually supposed. They are convinced that if such possibilities are thought of, if the history is taken carefully, if the physical examination is complete, with, of course, careful study of blood or even of spinal fluid, if indicated—that an increasing number of gastro-intestinal lesions regarded as due to other causes, will, in reality, be shown to be syphilitic in origin.

Pneumonias Following Injection of Arsenobenzenol.—Nine patients who had syphilis were injected with exactly the same solution and technic, each having an immediate reaction which was followed by a broncho-pneumonia. All patients were critically ill, extreme dyspnea being the outstanding feature. The recovery was complete in each case.

Archives of Internal Medicine, Chicago

Aug. 15, 1919, 24, No. 8.

- *Immunity of City Bred Recruits. A. G. Love and C. B. Davenport, Washington, D. C.—p. 129.

Immunity in City Bred Recruits.—In mobilization camps, communicable diseases have produced the least admission and death rate in those camps which drew from areas that were prevalently urban. Love and Davenport base this conclusion on the studies made of measles, mumps, lobar pneumonia, cerebrospinal meningitis, scarlet fever and influenza. The explanation given of this relation is that recruits from prevalently urban territory had acquired immunity through having had the disease in their youth. However, this hypothesis does not cover the case of the rarer diseases of childhood, such as cerebrospinal meningitis. Another hypothesis is that the immunity is due to a selective elimination of susceptibles. It is assumed to be greater in densely populated than in sparsely populated areas. This hypothesis fails, however, to account for immunity in the case of mumps which does not kill children. Another hypothesis is that life in urban communities produces a general resistance to disease of which the observed resistance to measles, mumps, lobar pneumonia, cerebrospinal meningitis and scarlet fever are only special instances. Many collateral facts speak strongly for this hypothesis.

Influenza. Both the length and detail of this article preclude a brief abstract. However, a few of the authors' findings may be emphasized. For instance, the incidence of influenza is greater among whites than among negroes, but the mortality rate is higher among the latter. The anatomic and bacteriologic findings vary with the stage of the epidemic and of the disease and depend to a certain extent on the endemic bacterial flora. Influenza produces widespread changes throughout the body, and while the lungs command present the most spectacular lesions, pronounced alterations are also encountered in the nervous, cardiovascular and other systems. The most general changes produced by influenza are pronounced congestions, hemorrhages, toxic degenerative lesions and hemorrhagic inflammations. The true pneumonitis of influenza is characterized by extreme proliferation of pulmonary epithelium, pronounced hyperemia and hemorrhages. The commonly present secondary invaders produce a pneumonitis which grossly and microscopically consists of a number of separate, dissimilar pathologic processes. Throughout the disease there is a relative paucity of polymorphonuclear leukocytes and a proliferation of the lymphoid tissue; this would seem to point to myeloid intoxication and to lymphoid stimulation. Chronic influenza is characterized by relative absence of vascular changes, connective tissue proliferation and diffuse suppuration. The influenza bacillus, although not found in every one of the 126 cases analyzed was present in a sufficiently high percentage, and often enough in acute fatally ending infections, for the authors to consider it, if not the prime cause, at least the most important indicator of epidemic influenza. As the patients lived longer and the epidemic progressed, bacterial agents, well established as the cause of respiratory tract disease, notably the non-hemolytic streptococcus and pneumococcus, appeared as secondary invaders and modified the bacterial readings and anatomic changes. It is noteworthy that all the secondary invaders were more fatal in symbiosis than alone. Later in the epidemic the hemolytic streptococcus assumed the ascendancy as a tertiary invader, crowding out the secondary invaders, and was of special importance in cases of long duration. Staphylococcus and *M. catarrhalis* made then appearance toward the end of the epidemic and to some extent modified the pathology.

Tuberculosis and Irritable Heart. No evidence has been found by King that there exists more than accidental relationship between irritable heart and pulmonary tuberculosis.

Extract Nitrogen in Tissues. The data offered by Foster are neither complete nor conclusive. The evidence at hand simply supports an inference that has always been made, namely, that retained nitrogen cannot be retained exclusively in the blood. There seems also a possibility that disturbances of protein metabolism is a characteristic of nephritis generally, and that difference with types of nephritis are differences only of degree.

Formation of Single Ovum Twins.—Streeter suggests that a careful search at the placental attachment of the umbilical cord would frequently reveal the presence of minute epithelial vesicles the remains of stunted twins, showing that the tendency toward twinning in man is even greater than is now supposed.

Changes in Skin Sensitiveness to Tuberculin During Epidemic Influenza.—During the recent epidemic of influenza Bloomfield and Mateer were struck by the remarkably low leukocyte counts encountered even in mild or ambulatory cases. This suggested that at least some of the reactive processes of the body were in abeyance. It seemed of interest, therefore, to study skin sensitiveness in this disease. The present report deals with the results of cutaneous tuberculin tests in nineteen consecutive cases of epidemic influenza. The diagnosis was based on the symptoms, the presence of hyperemic phenomena of the skin and mucous membranes, the character and duration of the febrile reaction, and the leukopenia. Most of the cases were mild and the disappearance of the skin reaction was therefore in no way associated with general collapse. Three of the patients developed bronchopneumonia, but all made uneventful recoveries. None of them showed clinical signs of active tuberculosis. Old tuberculin was used. Two drops were placed on the forearm about 5 cm. apart. Linear scarification with a dull scalpel was done through the drops of tuberculin after a control scratch had been made distal to them. The tuberculin was allowed to dry on the arm. The tests were all made by the same observers and read at one, two and three days intervals, the character and extent of the redness and induration being noted. Tests were done during the febrile stage and after the temperature had become normal. Skin sensitiveness to tuberculin was absent in every case but one, both mild and severe, during the febrile stage. During convalescence reactivity returned in 89.4 per cent. of the cases, which corresponds to what one would expect in a group of normal individuals of the same age. The return to maximum reactivity was gradual in most cases, as shown by successive tests. In two patients a positive skin test was not obtained during the period of observation, even after the temperature had been normal for from six to eight days.

Hemorrhage Into Postscarlatinal Cervical Abscess.—Following a severe attack of angina, diagnosed as diphtheria by the attending physician, a diffuse, dull, red macular papular rash appeared. The patient was considered by her physician to have nephritis following diphtheria and thus came under Rivers' care. Part of the tonsil, soft palate and posterior pillar on the right side had sloughed, leaving a ragged hole lined with greenish white pus. The glands on both sides of the neck were enlarged. There was a mass the size of a lemon, deeply situated below the angle of the jaw on the right side, that was obscurely fluctuating and was obviously an abscess. The cervical abscess was opened by means of a small puncture and at least 2 ounces of pus were obtained from which a hemolytic streptococcus was grown. The patient seemed to be doing well for three days, when she was found in a large pool of blood, exsanguinated, pulseless and gasping for breath. The bleeding had stopped spontaneously and the wound was not disturbed. There were two hemorrhages in the morning of the following day. At 1 p. m. blood began to spurt from the wound. The resident surgeon enlarged the incision into the abscess and found an erosion of the internal and external carotid arteries and of the internal jugular vein and that the hemorrhage was from these three sources. A heparin was placed around the common carotid artery and the bleeding from the internal jugular was controlled by packing. There was sugar in the urine for one week after the operation, but the blood sugar was always normal. The patient developed generalized edema, insensibility to pain, waxy flexion, Chvostek's sign, a double Babinski, exaggerated reflexes, double ankle clonus and a distinct loss of memory for recent events. Gradually she

improved. The wound healed slowly under treatment. Rivers calls attention to the fact that adenitis with abscess formation, especially about the neck, is one of the complications of scarlet fever.

Analysis of Cerebrospinal Fluids of Cats with Meningeal Infections.—A method is given by Felton for the measurement of protein in the cerebrospinal fluid. It has been found to be of as great value in acute meningeal infections as the Pandy or Ross Jones tests in differentiating the cerebrospinal fluid of normal cats from those with chronic lesions in the central nervous system. It is simply a Micro-Estach, consisting in the precipitation of the protein of 1 c.c. of cerebrospinal fluid in a small graduated tube by means of 0.8 c.c. of Tsuchiya's reagent. The test is described in detail.

Treatment of Hay-Fever by Alcoholic Injection.—Trowbridge injects 95 per cent. alcohol directly into the turbinate, also into the sides of the septum. The treatment is somewhat painful, even though the nasal cavity has been anesthetized thoroughly. There is no pain at the entrance of the needle but on the injection of the alcohol into the tissues the patient complains of considerable pain for a few moments at each injection, provided the alcohol is properly injected. Several injections should be made on each side, considerable reaction following the treatment, lasting from two to seven days. Relief from sneezing is usually immediate. Trowbridge usually prescribes an antiseptic spray to relieve the congestion.

*Production of Antihuman Hemolysin. E. B. Vedder, U. S. Army.—p. 141.

Effect of Agglutinins.—The experiments reported by Fujimoto showed that the glycolytic action of the living *B. coli* may be markedly weakened by agglutinin, and that the agglutinin is able so to change the cell membrane of the bacteria that their endoenzyme can permeate it. Neither agglutinin nor hemagglutinin alters the permeability of bacteria and red blood corpuscles for glucose. The resistance of the blood corpuscles to hypotonic solutions is slightly decreased by agglutinin or hemolysin.

Hemolytic Complement and Antibodies.—A method for the collection of plasma is described by Watanabe which has yielded uniform success and simplified this difficult technical problem. This technic involves the use of dried sodium oxalate after a method devised by Mecker, and a paraffined tube. Sodium oxalate in the proportion of 0.001 gm. per cubic centimeter of blood prevents coagulation and does not exert any injurious influence on hemolytic complement or antibodies; in amounts of 0.004 gm. per cubic centimeter of blood sodium oxalate may prove to be antielementary. The oxalated plasmas of normal and syphilitic persons and normal and immunized rabbits contains hemolytic complement in the same or somewhat greater amounts than the corresponding serums. The oxalated plasmas of syphilitic persons contain the same amounts of Wassermann antibody as the corresponding serums. The oxalated plasmas of persons and rabbits contain the same or occasionally slightly greater amounts of such natural antibodies as antishrimp hemolysin and typhoid agglutinin as the corresponding serums. The oxalated plasmas of normal and immunized rabbits contain as much specific and non-specific complement fixing substances and specific bacterial and hemagglutinins as the corresponding serums. The general conclusion reached by Watanabe is that hemolytic complement and natural and immune antibodies exist free and performed in the circulating plasma of the blood.

Nature of Eclampsia.—Ohata's investigation showed that in its capacity to neutralize the poisonous action of placental extract the serum of eclamptic women is much inferior to that of normal individuals, whether male or female, and that the normal capacity of the serum, in this respect, is restored, in eclamptic women, on the fourth or fifth day after labor. The investigation showed also that this abnormality of the serum in eclampsia is not brought about by the convulsion itself. Furthermore, not only was a marked resemblance pointed out between the symptoms produced with the placental extract and those of the eclamptic attack, but an almost perfect agreement has been found between the anatomic features of eclampsia and those of the animals which were killed by repeated injections of placental extract. From these facts Ohata feels justified in drawing the conclusion that the true nature of eclampsia is nothing other than an intoxication by the placental poison which is made possible by a weakening in its normal capacity of neutralization on the part of the maternal blood.

Production of Antihuman Hemolysin.—Vedder has found that the hemolysin is either a globulin or is precipitated with the globulins; more probably the former hypothesis is correct for the total hemolytic power of a serum is contained in the globulins whether precipitated out by salting or by dialysis. In this case, therefore, an antigen consisting of a specific albumin produces an antibody consisting of a specific globulin.

Apical Tuberculosis and Orthograde Posture.—The hypothesis formulated by Phillips may be stated thus: In the assumption of the orthograde posture, gravity causes the bulk of the blood of the pulmonary circulation to flow through the lower portions of the lungs; the capillaries of these portions are filled to a certain degree of overdistention, while the capillaries of the upper portions, particularly the apexes, are but meagerly filled with blood and their walls are more or less collapsed; the resultant being that conditions are produced which afford opportunity for the lodgment and development of the tubercle bacillus in one or more ways. As a lemma to this hypothesis, if under the hydrostatic conditions imposed on the circulatory mechanism by the assumption of the upright posture the organism is able to maintain a certain minimum circulation through the apexes of the lungs, apical tuberculosis will not develop, and, as a corollary, pulmonary tuberculosis as a primary disease will not occur. However, Phillips says, this hypothesis should not be taken too rigorously, because we must admit that there is still question as to just where it is essentially a lesion of the pulmonary parenchyma or an extension by way of the lymphatics from the lymphatic glands, or by the blood stream from these glands, or from some other primary focus elsewhere, and, finally, whether there is any locus of the lungs more peculiarly susceptible to tuberculosis than another.

Neurocirculatory Asthenia. Among soldiers and civilians one frequently encounters persons with congenital, often hereditary nervous instability. This Boas continues, may manifest itself in different ways, giving what may be called

a cardiovascular, a gastro-intestinal, a mental and a respiratory syndrome. These patients are unable to withstand unusual strains or stresses, be they physical or mental. In children one meets a similar condition in orthostatic albuminuria. It is essential to recognize the close interrelationship of these symptom complexes, and their occurrence in unstable individuals, who often conform to a distinct body type.

Retention of Habits by Rat After Partial Decerebration.—The question propounded by Franz and Laschley and which led to making the experiments reported in this paper, viz., Do rats retain habits of recent formation after the destruction of certain cerebral regions? is answered in the affirmative. Rats were taught to ramble through a simple maze and then portions of the anterior cortex were removed surgically. Later the rats were placed in the maze and their actions noted. It was found that the rats which were not overtrained required 29 per cent. less time for the first fifteen trials after the destruction of the frontal lobes and made 53 per cent. fewer errors than they did in learning the maze. This in itself is evidence for a partial retention of the habit. In fact, as a whole, the experiments show that in the white rat the removal of large parts of the frontal portions of the brain does not greatly interfere with a learned reaction. The authors regard this as being the more remarkable since it seems probable that the so-called motor area is in that region and that in most, if not all, of the cases there was a destruction or abolition of the motor connections. While it cannot be concluded with certainty, yet it seems likely that the motor derangements which were exhibited by many of the rats were due to the interference with the normal efferent impulses and not to the general anemia (from the hemorrhage of the operation). Some of the animals also showed obvious disturbances of sensibility, the observations indicating that in some the stimuli to the vibrissae and olfactory stimuli did not give normal effects. In view of the importance of these two forms of sensibility in the rat's reactions, the authors are led to wonder whether these retain their preimportance in the animal's learned activities, or are replaced by other forms of sensibility, such as the general kinesthetic. Although the results give plain evidence of non-interference (relative, to be sure) with learned reactions when the frontal portions of the brain have been destroyed they also suggest that the habit reaction is not necessarily cortical in these animals.

Action of Opium on Psychologic Reaction Time. The experiments reported on by Macht and Isaacs were made on twelve normal subjects. They used morphin sulphate, narcotin hydrochlorid, narcophin and pantopon or pantopium. They found that the effect of morphin alone and in combination with other opium alkaloids depends on the dose used and may be manifested by a change in the mean reading, a change in the mean variation of the readings, or by both of these; and in case of association tests, by the number of errors made in performing a mathematical calculation. After small doses of morphin, there is generally a primary stage of stimulation or quickened reaction time; this may or may not be followed by a secondary stage of depression, as indicated by narcosis and prolongation of the reaction time. After larger doses of morphin, the primary stimulation stage is very short and may be overlooked, whereas the secondary stage or stage of depression is predominant. From the experiments made with combinations of morphin with other opium alkaloids in the form of narcophin and pantopon, it appears that morphin given in such a form is more narcotic and correspondingly more depressant to the psychic functions than when the same dose of morphin is administered to the same subject by itself.

Cerebral Motor Control.—Seven cases of hemiplegia produced artificially by Ogden and Franz in four animals were treated in different ways in order to determine some of the conditions favorable to the recovery of voluntary motor, one experiment shows that motor recovery after the production of an hemiplegia does not result if the animal is left to its own devices. Even though the animal be prevented from using the sound (unparalyzed) segments there is little difference in the improvement from that in which no treatment is given unless in addition to the limitation of the possibility of movement there be added some extra stimulation to the muscles and nerves of the paralyzed side, although the recovery is rapid in such a case if treatment by muscle stimulation and nerve vibration be directed to the involved parts and if special stimulation exercises be given to the animal which will provoke the animal to move the paralyzed segments. The method of treatment recommended by neurologists, general massage, does produce a slight amount of improvement but not to an extent to enable the animal to use the arm and hand properly for such ordinary operations as feeding and climbing, although these activities may be carried out after such treatment in an awkward manner. When, however, efforts are directed to the special nerves and muscles, and when the sound side of the animal is restrained so that movements of climbing and feeding must be made, if at all, by the use of the paralyzed segments, the improvement is rapid and the recovery is practically complete. One fact that stands out prominently is that recovery from the hemiplegic state may be very rapid. The results of these experiments also suggest a reconsideration of the whole problem of cerebral motor control and especially that of cortical motor control.

Cerebral Function in Partially Decerebrated Rats.—Rats were trained after destruction of various parts of the cerebral cortex, including the frontal, temporal, parietal, and a large part of the orbital surfaces and the influence of the cerebral destruction on their ability to form and retain kinesthetic-motor habits was tested. Laschley and Franz found that the habit of turning correctly in the simple maze may be retained after the destruction of any part or all of the cortex lying in front of and above the knee of the corpus callosum and after the destruction of any part of the temporal and parietal regions. The maze habit may be acquired after the destruction of all the cortex included within these areas, and after the destruction of one, perhaps both, of the striate nuclei. The more complex habits involved in opening an inclined plane box are retained after destruction of the temporal regions of the cortex. The complete destruction of the frontal regions of the cortex results in the loss of the inclined plane box habit. The partial destruction of the frontal region does not abolish this habit. So long as the destruction of the frontal pole is not complete the habit is retained, apparently irrespective of what part of the frontal region has been destroyed. No marked motor disturbances appear after the complete destruction of the stimulative areas of the cortex but in certain cases marked hemiparesis seemed to result from the destruction of the corpus striatum.

Coordination of Measures for Prevention and Treatment of Tuberculosis. J. M. Martin. p. 119.
Care of Tuberculous Children. W. Aston. p. 124.

Tuberculosis and Ministry of Health.—A plan is suggested by Wingfield by which special attention would be given to tuberculosis. The ministry of health will naturally be the supreme head and should contain a section to deal with tuberculosis, and nothing but tuberculosis, though its own work overlaps that of other sections, thus providing unity of command for tuberculosis and cooperation of the tuberculosis campaign in the general public health scheme. A suggested outline of the governing body of the tuberculosis section would be: administrator, the chairman; financial adviser; medical adviser, who should be the chairman of an advising committee selected from working officers elected in rotation, holding office one, two or three years; and social adviser, to be the chairman of an advising committee selected from working officers elected in rotation, holding office one, two or three years. Having satisfactorily constituted the central governing body, the work and responsibility should be decentralized, and placed on the shoulders of decentralized units. The decentralized unit should be: (A) Tuberculosis officer; aftercare worker; nursing staff. (B) Sanatorium officers; aftercare worker; nursing staff. The units must be uniform all over the country. Local homes for advanced cases must be attached to each unit. Homes for the dying are needed, but they need not be definitely local. Working colonies should be provided and placed under the care of the local unit. The important point is that there should be sufficient numbers of these establishments, if they are to be of practical value to the whole scheme. And, arising from this, it seems certain that this or any other scheme will be useless unless hospital and sanatorium beds in ratio to the number of patients are provided before the scheme is introduced to the public.

*Ankylostomiasis in London. C. H. Warner. p. 105.

Hospitals for Tuberculosis.—Shaw pleads for greater facilities for the hospital care of tuberculous patients and for the establishment of institutions, invalid homes, where those patients who are rendered incapable may be nursed and treated until they are fit to earn their living or until they die. Such institutions being in the heart of populous centers, and not buried in the country, will allow these invalids to be near their families, without being a burden to them. The opportunities for the study of the disease will be greatly enhanced, and the need for the discovery of better methods of treatment than the present will be better advertised. There will develop quite a definite body of nurses who have been trained in tuberculosis. A saner view will be held about the dangers of contracting the disease by contact, and nurses will not shun the work. The rich who do not wish to send their tuberculous relatives from their homes will be enabled to secure the help of these nurses for home treatment. The scheme would make no attack on the present plan of providing sanatoriums for the poor, or for the rich. Shaw says that to the cry "decent homes for the poor" must be added "decent permanent hospital accommodation for those who are laid aside by pulmonary tuberculosis or any other disease which has reached an incurable stage."

Eclampsia.—In the treatment of eclampsia Smith says that cesarean section performed by an experienced operator is one

of the safest operations in surgery for the mother, and that it enormously increases the chances for the child, if performed after the end of the seventh month when the child is viable. The best time to operate is before labor begins and before the woman has been examined by an uncleaned hand. There must be three doctors and a good trained nurse if every patient is to be saved. If the proper conditions cannot be obtained at her home, it is better to send her to a good obstetric surgeon at a good hospital.

Ankylostomiasis in London.—Warner records a case of ankylostomiasis in a subject who has neither been abroad nor resided in a mining district. The patient had never been out of England, nor had he visited Cornwall or any other mining district; he had not, in fact, travelled farther from London than Dover. The boy had, however, associated to a considerable extent with soldiers who had been abroad, and it is possible that he acquired the ankylostoma infection in this manner.

*Value of Solid Paraffin Wax in Local Surgery. S. Mort. p. 105.
*Expectation of Life in Pulmonary Tuberculosis, with Special Reference to Pensions Assessment. R. M. F. Picken. p. 106.
*Lymphocyte and Its Clinical Significance. A. K. Gordon. p. 108.

Traumatic Rupture of Intestine.—A case of rupture of the jejunum with laceration of the mesentery and intraperitoneal hemorrhage is reported by Battle. The patient was thrown from a bicycle by a van. At operation Battle found a large transverse rupture of the jejunum about 6 inches from the duodenojejunal junction and extending over five-sixths of the circumference of the bowel, there being only a strip of the mucous membrane on the mesenteric aspect which appeared normal. Excision of this part was performed, for a distance of 3 inches above and 3 inches below the rupture, and an end-to-end union made. The boy recovered.

Expectation of Life in Tuberculosis. According to Picken the expectation of life of males, aged, on the average, 30 years, notified in Glasgow as suffering from pulmonary tuberculosis is about three and one-half years. The expectation of life of males at a sufficiently early stage of the disease to raise hope of recovery is about six and one-half years. The expectation of life of male sanatorium cases discharged with the disease "arrested" is estimated at somewhere about fourteen years. The normal expectation of life of all males in Glasgow at the age of 30 years may be taken as thirty years, but was probably higher for the period covered by this inquiry. The above calculation, applied to the assessment of soldiers and sailors discharged with pulmonary tuberculosis, justifies a minimum assessment of from 50 to 60 per cent., and this should apply to men in whom the disease appears to be arrested for the time being. All cases where the disease is actively progressive, as measured by general signs and symptoms, physical signs, bacteriological and roentgen-ray examination, should be assessed at 100 per cent. disability. All others, i. e., cases of low activity such

as those of the chronic fibroid type, should be placed in one grade at 70 or 80 per cent. disability.

Lymphoidocyte and Its Clinical Significance.—Gordon is of the opinion that the lymphoidocyte has clinical significance and suggests that it should be looked for in every case as a possible point of value in diagnosis. He has found these cells in the blood of cases of diabetes and cancer but not in influenza pneumonia or aortic disease.

*History of Obstetrics in France. P. Bar.—p. 3.

*Indications for Medical Abortion. II Henneberg.—p. 20.

Influenza at Paris Maternity. P. Pellissier. p. 28.

French Contributions to Obstetrics.—Bar's historical references confirm that podalic version was first placed on a scientific basis by Paré in 1550, cesarean section by Rousset in 1581; the forceps, invented in England, was first made practicable by Levret in 1747, and in 1768-1777 Sigault conceived the idea of and performed an operation to enlarge the pelvis. Scientific embryotomy also dates from Baudelocque, 1829, and Tarnier's forceps, basiotribe and embryotome from the eightsies. It was at the Paris Académie de médecine, March 11, 1879, that the alleged multiple causes of puerperal fever were being discussed when Pasteur swept them all aside saying, "Ce qui cause l'épidémie, ce n'est rien de tout cela; c'est la médecine et son personnel qui transportent le microbe d'une femme malade à une femme saine." Hervieux remarked that he did not expect to live to see this wonderful microbe, but Pasteur seized the chalk and drew on the blackboard a streptococcus saying: "Tenez, voici sa figure." Bar adds that there had long been a growing consciousness of the contagiousness of puerperal fever, but Pasteur's four words and chalk drawing brought action, and banished from the world the puerperal epidemics of the past. France also took the lead in welfare work for pregnant women and nursing mothers, and for young children. By instruction of the pregnant and giving a shelter to those in need, an actual science of prophylactic obstetrics has been evolved. Shoulder presentation has practically disappeared, and celampsis is very rare. To Budin is due the inauguration of the well baby clinic and systematic prenatal care and instruction, while Rousset put through the law for the protection of young infants. Bar declares that this latter is no longer regarded as a charity, but as a state measure vital for the self-preservation of the nation. The question now is how to lighten for working women the burden of child bearing. This opens a new chapter in the history of obstetrics, and here, too, France is making headway.

Medical Abortion.—Henneberg classifies the eighty-one cases in which abortion was induced as a therapeutic measure during the last twenty-five years at the gynecologic clinic at Geneva. Since 1900 all the women with uncontrollable vomiting have been taken from their environment, isolated and kept on a suitable diet, and in all the tendency to vomiting subsided completely. Consequently this is no longer regarded as calling for induction of abortion. In thirty-one cases the abortion was done on account of pulmonary tuberculosis, in fifteen for heart disease. One woman was becoming blind from choroiditis aggravated by each of her four pregnancies, and the ophthalmologists sent her to the clinic to have a new pregnancy arrested and the woman sterilized.

Bulletin de la Société Médicale des Hôpitaux, Paris

*Jaundice Secondary to Influenza. Roussel and de Lavergne. p. 587.

*Influenza. P. Mellé.—p. 590.

*Cardiovascular Symptoms After Gassing. A. Clerc and Rousselot. p. 593.

Jaundice Secondary to Influenza. Roussel and Lavergne report five cases of what they call "jaundice from liver-kidney derangement," secondary to an influenza pneumococcus infection. The pneumococcus was cultivated from the blood even at the height of the jaundice. As we know that bile has a potent bactericidal action on the pneumococcus, we must assume that in this case the jaundice cannot be the result of retention of bile salts but only of the bile pigments.

Cardiovascular Symptoms in the Gassed.—Clerc and Rousselot conclude from this study of 396 *ypérités* that the cardiovascular apparatus does not seem to be primarily nor especially affected by mustard gas during the acute phase of its effect. When the myocardium weakens, it is secondarily, under the influence of the progressive asphyxiation or superposed infection. Sequelae in heart and vessels are rare and insignificant in comparison to the sequelae in the lungs and the condition of attenuated infection which persists so long in the gassed. In the discussion that followed, Rist remarked that emphysema was constant in all the gassed sent to him for his specialist verdict. This emphysema and chemical bronchitis hamper functioning, and are an obstacle to physical work. The ultimate outcome can only be surmised at present. In some there has been no improvement in more than two years to date. The prognosis therefore has to be reserved. He advises temporary discharge from military service with pension calculated on a reduction of 30 or 40 per cent. in the earning capacity. Sergeant in examination of more than a thousand gassed soldiers has been impressed with the frequency of emphysema and chronic bronchitis. There is often also a cough like that of whooping cough. There is probably a bronchopulmonary sclerosis responsible for this. Most of such cases are classed as tuberculosis suspects, but tuberculosis seems to be absolutely exceptional in the gassed.

*Pathology of Pott's Disease. Ménard.—p. 270.

*The Dermographic Pencil. H. Bèclère.—p. 272.

Osteogenesis After Wounds of the Head.—Lemaître declares that among the traditions overthrown by the war is the assumption that the periosteum alone is responsible for the generation and regeneration of bone tissue. This does not occur unless there is a layer of bone along with the periosteum, no matter how thin this layer of bone may be. This *ostéo-périoste* is what can be counted on for growth of new bone in situ, and with pedunculate and free bone-periosteum flaps. He gives an illustrated description of cases in which extensive gaps in the upper or lower jaw and skull grew up completely in time. Similar success was realized in reconstruction of the bony framework of the nose with a bone-periosteum implant from the tibia. Even when healing does not occur smoothly, the graft may regenerate as effectually as under normal conditions. Lemaître is an otolaryngologist, and his article was read at a conference held by the Vichy American Medical Society which specializes in maxillo-facial reconstruction work.

Horizontal Displacement with Fracture.—This title is expressed in the French term *décalage*. It is discussed here in relation to radiography of fracture of the humerus.

Evacuation Surgery.—Drevon and Petit comment on the transformation in the surgery of evacuation as the war went on. At first it was merely a wrapping up and packing on of the wounded men, but soon a complicated system of surgical aid was evolved which he describes in detail.

Dermatographic Pencil. Bèclère relates that just before marking the skin with the paper pencil, he wipes off the spot with a scrap of cotton just dipped into a small tumbler of gasoline which he always has at hand. The pencil then makes a very distinct mark on the skin thus lightly smeared with gasoline, and no pressure is required. He has found this a great help for dermatographic outlining in the last two years.

*Infectious Pernicious Anemia. N. Fiesinger, P. L. Wertheimer, and J. Meyer.—p. 89.
*Morbid Changes in Trochlea of the Humerus. P. Japiot.—p. 100.

War Wound of the Kidney.—Thévenot remarks that in his three years and a half of work in active sectors at the front he encountered only thirty cases in which the kidney had been injured by a projectile. The outcome in these cases shows that nephrectomy is rarely indicated.

Walking Treatment of Fracture of the Leg.—Collet refers to the use of Delbet's apparatus that allows the patient to be up and about. He extols it as superior to all other measures when the fracture affects the shaft only. Under other conditions, it should be used extremely cautiously or not at all, unless certain that there is no displacement or diastasis.

Regeneration of Bone.—In Duhamel's case the newly regenerated bone closed in two months a gap of 6 cm. in the shaft of the humerus. The bone tissue extended in width even beyond the shaft, but the shadow of course was not dense. In Lamare's case the gap of 8 cm. in the tibia rapidly grew up with bone tissue. He ascribes great importance to the walking cast, the play of the muscles stimulating repair and modeling the new bone.

Biologic Laws Governing Implants.—Bonnefon's views and experiments were reviewed recently, page 300. He reiterates that regeneration is by no means reviviscence.

Pernicious Anemia of Infectious Origin.—In the case described in minute detail the plastic pernicious anemia developed in the course of a suppurating pneumothorax for which the perfringens seemed to be solely responsible, after a shell wound of the chest. The rds dropped from 1,800,000 to 600,000 in six days, with subjaundice, but recovery followed under serotherapy, which arrested the infection, plus operative draining of the focus.

Paris Médical

July 12, 1919, 9, No. 28

- *Normal Alimentary Glycosuria. —Gilbert and A. Baudouin.—p. 29.
*Diet in Nephritis. A. Lémierre.—p. 34.
*Auscultation of Venous Pulse. M. Perrin and G. Richard.—p. 40.

Normal Alimentary Glycosuria.—Gilbert and Baudouin describe some minor points which have to be observed in testing the urine for sugar, or else the normal content in carbohydrates may prove misleading. For example, the precipitation of creatinin is not instantaneous; it is better to wait for an hour before filtering. They report comparative tests with various technics. In young and normal subjects the sugar content of the urine showed very little increase after ingestion of even large amounts of sugar, never surpassing 0.50 gm. If 1 gm. or more is found, this may be regarded as a sign that the assimilation of sugar is more or less defective. Even minimal hyperglycosuria of this kind may reveal slight disturbance in the metabolism, and hence the importance of a technic of precision to disclose it. The carbohydrates in the urine are complex, not merely sugar alone. They think that the pentoses form most of the reducing substances; the reducing fermentable fraction is not glucose. The best we can do at present is to accept the global figure of the carbohydrates.

Diet in Nephritis.—Lémierre remarks that the discovery of the harmfulness of salt in certain forms of nephritis is one of the most surprising discoveries of recent years. Patients with extreme edema, such as used to be pitilessly restricted to a milk diet over long periods now are seen to improve and thrive under Vidal and Javal's menu yielding 1,500 calories. It is made up of 200 gm. bread made without salt; 200 gm. raw meat; 250 gm. potatoes; 50 gm. sugar, and 30 centiliters each of wine and coffee.

With dry uremia, in distinction to uremia with dropsy, Achard and Paiseau recommend a menu containing 50 gm. meat; 200 gm. potato; 100 gm. rice and 50 gm. butter, representing 1,630 calories. If there is no abnormal retention of salt, it is unnecessary to restrict the intake of salt. The intake of water should never be less than 1.5 liters as the kidney may not be able to eliminate the urea unless it is well diluted; the polyuria therefore is necessary. In acute nephri-

tis there is retention of all the elements of the urine, and hence substances that produce these elements must not be taken, while water should be given freely to flush the kidneys. Nothing but water should be allowed, but some of it may be sweetened or flavored with fruit juices; "the sugar affords a few calories while not giving the kidney a molecule to eliminate." The restriction to water should be maintained along with local and general bloodletting, cold enemas and purgatives until the *débâcle polyurique* sweeps out the urea and chlorids that have been retained.

Auscultation of Venous Pulse.—Perrin and Richard describe the most effectual technic for this and interpretation of the findings. They urge that every practitioner should familiarize himself with such procedures and not content himself with regarding admiringly from afar the cardiologic studies of the day. The contraction of the auricle is manifested in the jugular pulse wave as (a) corresponding to the first jugular vein sound on auscultation and the upper third of the ascending line in the oscillogram tracing of the humeral pulse. The contraction of the ventricle (c), the second vein sound and the peak of the oscillogram line correspond to the apex beat, while the beginning of the diastole (v) corresponds to the third vein sound and the lower third of the descending oscillogram line. The record is thus obtained with the eye, the ear, the oscillogram and the hand (apex beat).

Presse Médicale, Paris

July 10, 1919, 27, No. 39

- *Cancer of Body of Uterus of Placental Origin. F. Jayle and L. Halperine.—p. 384.
*Roentgen Examination of Tuberculosis Suspects. G. Déré.—p. 384.
*Electric Treatment of Degenerated Muscles. H. Langier.—p. 385.
*Symptomatology with Transverse Section of the Spinal Cord. Denker.—p. 386.

Cancer of Body of the Uterus.—Jayle and Halperine prefer this term instead of "chorio-epithelioma," "syncytioma" or other terms which are confusing to all except histologists. These cancers are peculiarly liable to sudden and profuse hemorrhage and to metastasis. Their illustrated description of the structure explains these two tendencies. In a case reported there was evidence of inherited syphilis.

Roentgen Examination of Tuberculosis Suspects.—Déré found in 80.2 per cent. of the 844 soldiers sent to him as suspects that the assumption of tuberculosis was not sustained by the roentgen findings. In these 676 negative cases, the bacteriologic findings were always concordant. The apex shadow frequently looked opaque and grey, but it cleared up and kept clear when the man coughed. By having the subject lean forward or to one side, the second interspace comes into view when otherwise it is hidden by the shadow of the clavicle. In some of the cases with positive findings they need not necessarily be of a tuberculous nature. In 40 per cent. of the positive cases there was a pleural reaction at the base. Some of the cases also presented the findings characteristic of hilum tuberculosis with a glandular focus, such as has recently been described in children. Three illustrations show the typical findings.

Electric Treatment of Degenerated Muscles.—Langier remarks that the degenerated fibers become so irresponsive to the electric current that, in order to act on them, such strong currents have to be used that the sound muscle fibers suffer from them. This can be avoided by using a weak current and only very slowly increasing its strength. By this means the degenerated muscles are acted on electively. The degree of excitability of a muscle fiber is determined by what he calls the *chronaxie*, that is, the interval before the muscle fibers respond to the stimulus. For example, the muscle in the foot of a snail is a slow muscle, with high *chronaxie*, while the gastrocnemius in the frog is a rapid muscle, with low *chronaxie*. If a very slowly increasing current is sent through these two muscles, the snail muscle will contract while the frog muscle will not. It is thus possible to apply the electric stimulus electively to the degenerated muscle fibers while keeping it below the threshold for the sound muscle fibers. He describes mechanical means to control the current to keep it of this slowly increasing type.

One may is to apply to the electrode condensers which retain the current so that it does not reach the electrode in full strength until after the condensers have been charged, and they can be varied at will.

Transverse Section of Spinal Cord.—Deniker outlines the new symptomatology of transverse section of the spinal cord as it has developed during the war.

The Lessons Learned from the War on Treatment of the Wounded
R. Dupont, p. 249.

Case of Pseudobulbar Paralysis. Langueix-Lavastine, p. 254.
Spa Treatment of Neuroses. Macé de Lépinay, p. 256.

Treatment of the Wounded in the War.—Dupont traces the evolution of the treatment of the wounded through the first two years of the war, when every one was trying to improve on the old methods. "The French," he says, "finally succeeded in transforming the whole treatment of wounds and obtaining results hitherto undreamed of. Excision as soon as possible, followed by primary or secondary suture, cured the wounded so fast and so completely that the undersecretary of state for the Army medical department said that we had carried on the war with our wounded (*moins actions fait la guerre, avec nos blessés*). The glorious year was thus 1916; the following years merely witnessed the perfecting of this method which is essentially French."

Asthma plus Mania after Shell Comission. R. Benon and G. Lerat, p. 244.

Edema of the Brain; Recovery after Craniotomy. A. Conjon and R. Duboué, p. 252.

Cortical Sensory Centers.—Piéron tabulates the details of twenty-one cases of war wounds of the skull with cortical anesthesia. His table confirms that certain skin sensory phenomena have exact separate centers or a special region in the cortex. The sensations of pain, temperature and deep pressure are modified last. He discusses in detail the sensory rôle of the cortex, the separation of sensory and motor centers, the sensory representation in the cortex of different segments of the surface of the body, and the proportional representation of the different forms of sensation and perception.

Pneumococcus Pseudotuberculosis.—Lorrain and his co-workers describe seven cases in which the diagnosis of pulmonary tuberculosis seemed certain, and the symptoms dragged along for months, but the sputum did not show tubercle bacilli, and conditions finally returned to clinically normal. The congestion of the lungs and the bronchopneumonia passed through an acute phase and then into an interminable subacute phase, without complete defervescence, dragging along for months without any very pronounced signs of consolidation. The subject does not feel sick enough to stay in bed, but he looks badly until he takes a turn for the better and throws off the whole. The focus of congestion may be at the apex, simulating acute tuberculosis. Or there may be a focus of pseudobulbar focus at the base, suggesting the bronchopulmonary form of tuberculosis or chess pneumonia. Or there may be some old healed tuberculous lesion along with the recent sequelae of bronchopneumonia. Careful auscultation will reveal that the lesion at the apex keeps stationary, and that the lesion at the base or in the middle of the lung is growing smaller. The recent history of some pneumoniae infection will then give the clue in some cases, but in others nothing but the absence of tubercle bacilli clears up the diagnosis. The benefit from general treatment has long been landed. Hirtz urges treatment as for actual tuberculosis, with supervision of the functioning of the diaphragm, possibly belting the lower chest to thrust down the abdominal viscera. Radiotherapy has also been advocated to aid in the healing of pneumonia with incomplete resolution. Several pages of bibliographic references are

given, classified by prolonged or relapsing pneumonia, prolonged congestion, nontuberculous protracted fevers, pseudotuberculosis of nasal origin, and association of pneumonia and tuberculosis.

*Transfusion of Blood. G. Hotz, p. 992.

Influenza. K. Frey, p. 1006.

Hemorrhage in Yellow Spot in Parturients. J. Strehel, p. 1013.

Transfusion of Blood.—Hotz traces the history of transfusion of blood back to Cardanus' work, published at Basel in 1556, in which he suggested transfusion of blood from a person of good character in the hope to redeem the character of the otherwise hopelessly immoral. The French ambassador at London, he says, was the first to actually practice infusion in man, in 1657. In 1667 cases were reported in which blood from a lamb was infused, with recovery of the apparently moribund patient. Hotz concludes his dissertation on transfusion of blood by commending it as practiced at present as reliable and fully answering its purpose, although we must not in our enthusiasm forget that both for donor and recipient it is a powerful interference in the most intimate and delicate processes of the organism.

Circulatory Disturbances in Influenza. A. Fortunato, p. 856.

Filtrable Viruses.—Sampietro remarks that about fifty different kinds of filtrable viruses have been described, although not all of them have been subjected to rigorous tests. Pasteur suggested in 1881 that the virus of rabies must be beyond the scope of our bacteriologic technique, and Sanarelli in 1898 proved that the virus of myxomatosis infection in the rabbit was not modified by passing through porcelain that filtered out the smallest bacteria then known. Some spirilla, cocci and spirochetes pass through certain filters but they can be seen with the dark field microscope. The preferable classification of the viruses seems to be in three groups: the ultra-microscopic viruses; those with filtrable phases in the life cycle of microscopic parasites, and the actually filtrable bacteria and protozoa. A further classification is in filtrable viruses transmitted by insects, probably of protozoan nature; filtrable viruses of spirochete nature, and those of certain or presumed bacterial nature. He discusses each of these groups, specifying the viruses that belong to each and the relations between them and other bacteria.

The experiences in the recent epidemic of influenza have combined with other findings to sweep away as untenable the hitherto prevailing assumptions in regard to the nature and behavior of the filtrable viruses, so that science is all at sea again with nothing to anchor to at present. The only facts that seem to be established to date are that there is some connection between filtrable viruses and cell inclusions; that certain filtrable viruses form one phase of the life cycle of some protozoa; and that certain bacteria have been found which will actually pass through porcelain. Another fact which seems to be well established is that the extreme contagiousness and wide diffusion of certain infectious diseases are the work of a filtrable virus, but associated bacteria are responsible for the characteristic symptoms and the pathologic anatomy. These associated bacteria he calls "etiologic binomes," and ascribes immense importance to them as they are what determines the characteristic picture of the nosologic entity, while the filtrable virus is responsible for the contagiousness and the diffusibility of the infection.

Immediate Treatment of Gunshot Wounds of Joints. E. Bossa-Lac,

p. 191.

Bone Cysts. R. Poletti, p. 204. Cont'd.

Resection of Pylorus.—Tenani gives the details of a technique for resection of the pylorus which he has applied in two cases, and lauds as being free from the drawbacks of other methods. It provides for the normal course of the bile and pancreatic juice. This is accomplished by mobilizing the stump of the duodenum after the posterior gastro-entrostomy and resection of the pylorus; then this stump is sutured end-to-side to the efferent loop of the jejunum, a short distance below the point of the gastro-entrostomy. To mobilize the duodenum requires releasing the whole of it from the parietal peritoneum and the duodenohepatic peritoneum. The latter is incised the entire length of the second portion of the duodenum, and the gastrophilic omentum is also incised. The duodenum can then be pushed over to the median line and the stump brought down to the proper point. This brings the duodenum away from the danger zone of the vena cava, and the head of the pancreas and the common bile duct come with it. To ensure the correct slant to the duodenal stump so that the bile and pancreatic juice will have free outlet, he lifts up and sutures the duodenum to the stomach, at a point beyond the mouth of the bile duct. The lips of the incision in the mesocolon are fastened to the posterior wall of the stomach around the gastro-entrostomy opening. This technique, he says, wards off danger of perforation of the duodenal stump, and the physiologic course of the bile and pancreatic juice is restored, aided by gravity instead of forcing them to climb up the afferent loop. They also are poured out into the bowel only as the chyme is passed along. His success in his two clinical cases confirms the practical value of these theoretical premises. The article is not illustrated.

Annaes Paulistas de Med. e Cir., S. Paulo

March, 1919, 10, No. 3

*Treatment of Diphtheria at São Paulo, J. de Toledo Piza.—p. 49.

Treatment of Diphtheria.—Toledo Piza pleads for larger doses of antitoxin than those generally used, his tabulation of the cases of diphtheria at S. Paulo in the last ten years showing a constant decline in the death rate as the doses were progressively increased. In the non-operative cases, the mortality in the last two years was only 2.4 and 2.8 per cent, although the number of cases has progressively increased, from sixty-four in 1910 to 490 in 1918. In the sixty-six operative cases, the mortality was 34.8 per cent, but omitting those who died within twenty-four hours, it was only 17.3 per cent. The antitoxin should be given both by intramuscular and subcutaneous injection. In the graver cases a third should be injected by the vein. In mild and moderate cases 10,000 or 20,000 units may suffice but in the graver cases 25,000 or 30,000 must be injected. The whole amount is injected at practically the same time, and he would not hesitate to inject up to 35,000 units in very grave cases. Fractionating the doses is annoying to the patient and is less effectual than the large single dose.

*Effects of Radioactivity on the Blood, A. da Silva Mello.—p. 123

*Aborive Treatment of Syphilis, Z. Goulart.—p. 138

*Suprarenal Asthenia, J. M. da Fonseca.—p. 149.

Effects of Radioactivity on the Blood and Blood-Producing Organs.—Mello remarks that Scin's announcement in 1904 that he had cured myelogenous leukemia with roentgen exposures was spoken of at first by nearly every writer on the subject as a typical *bluff americano*. Even with all the research since, we know but little more of the true significance of the influence of radioactivity on the blood, the importance of the destruction of these formidable masses of leukocytes, and the significance of the prolonged leukopeny which is a manifestation of radioactive poisoning. The experimental research in this line has been done with doses far larger than are ever used therapeutically. The effects are so fulminating that no conclusions can be drawn from them to aid in treatment, but we have learned that the blood system is extremely susceptible to radioactivity. Even one brief roentgen examination may induce leukocytosis. The lymphatic follicles of the spleen and intestine wall are so

sensitive that even five seconds of exposure to a capsule containing 20 mg. of Ra B may induce serious changes in the cells.

These and other facts cited emphasize the necessity for systematic reexamination of blood during roentgen or radium treatment. The degree of leukopeny is an index of the intensity of radiotherapeutic action as it affects the inmost recesses of the blood producing organs. Mello's own research with thorium X showed that the leukocytes might disappear completely from the peripheral circulation and the weight rapidly run down while the reds might persist apparently unmolested in structure or numbers to the animal's death. The blood-producing organs showed, simultaneously, violent destructive processes and processes of normal repair. When the dose used was too large, in man or animals, there was liable to be violent diarrhea as the thorium is eliminated in part through the bowel. Another important feature of the effect of radioactivity is the serious tardy disturbance that may follow the subsidence of a tumor under radiotherapy. Absorption of the tumor masses poisons the whole organism, the patient cured of his tumor but dying from the cure or at least suffering from chronic intoxication.

The progress in averting superficial lesions from radiant energy now enables us to focus our attention on the possible internal injury therefrom, but very little has been published in regard to chronic injury of this kind, and scarcely anything on chronic injury of the blood-producing system. The most important feature of the latter is that the lesions of this system are not usually produced by the direct action of the radioactive substance. Some of the animals in his research showed no signs of leukopeny, anemia and loss of weight from the chronic intoxication, but a second injection of the radioactive substance—even a minute amount—brought on serious manifestations and speedy death. This could not be explained by cumulative action, as the animals long since had eliminated the thorium X, and as thorium X loses all its radioactive properties in about four days.

He often found hyperplasia of the bone marrow accompanying the leukopeny, and hence the latter cannot be regarded as a sign of destructive processes in the blood-producing organs. The reds and the hemoglobin content may be apparently normal even with pronounced leukopeny, and they may regenerate normally after vascenectomy although the organism may be suffering severely from the chronic intoxication left by the radioactive substance, as evidenced by the extreme leukopeny and emaciation. An animal stands the toxic action of thorium X better after it has been bled several times; it may even increase in weight, instead of the otherwise almost inevitable loss in weight. The fact that the reds keep at the normal figure is due to stimulated production, as the reds are unquestionably destroyed under the influence of the radioactivity. The spleen plainly shows the exaggerated destruction of reds, and the pigmentation from this was noted in the spleen even when there was no anemia, confirming the superproduction of reds which conceals the massive destruction going on.

With the chronic intoxication, the spleen showed also regressive changes, but when there was associated infection, the spleen seemed to retain its normal structure or showed myelogenous transformation. This is especially interesting in view of the brilliant success that may be obtained by raying the spleen, especially in cases of myelogenous leukemia. Similar changes in the spleen have been observed in patients after raying of tumors, but the changes in the spleen have always been ascribed hitherto to toxic action from the tumor, and their true significance has been overlooked. Mello emphasizes that it is the salts of radium which have the most pronounced influence on the red corpuscle system, but there is a great difference between the various salts in this respect. For example, thorium X has a much stronger action on the myelogenous than on the lymphatic system; exactly the opposite of the roentgen rays, which act almost explosively on lymphatic tissues. The leukopeny under thorium X is mainly a function in the cells of medullary origin, that is, the polymorphonuclears, while the lymphocytes increase relatively in numbers. With the roentgen rays it is the lymphocytes which are electively destroyed,

This explains why in lymphatic leukemia thorium X may induce improvement for a time, but the hyperplasia of the bone marrow and the progressive anemia and the lesions encountered in the spleen amply explain the appearance of the refractory phase. After a series of apparently successful applications there is no further response, and the leukemia continues its fatal course. Mello's work with thorium X was done mainly at Berlin in 1915.

Abortive Treatment of Syphilis.—Goulart says that three unmistakable cases of reinfection after abortive treatment of syphilis have convinced him of the actual efficacy of modern treatment of this disease. He gives the details of those cases and treatment, and also of eight other cases in which the cure seems complete but there has been no reinfection.

Suprarenal Asthenia.—Da Fonseca presents an array of evidence to prove that the muscular weakness in certain conditions is the result of insufficiency of the suprarenal medulla and entire chromaffine system, and only secondarily of the suprarenal cortex. Epinephrin therefore is the treatment par excellence.

*Treatment of Congenital Talipes Varus Equinus. P. Borobio y Diaz.—p. 257.

*Spengler's Immune Bodies in Treatment of Tuberculosis in Children. C. S. de los Terreros.—p. 263.

*The Rachitic Pains. V. Juristis.—p. 286.

Congenital Pes Varus.—Borobio insists that this deformity, which is always accompanied with more or less equinus deformity, is amenable only to surgical measures. If they are applied early, all that is necessary is the Phelps-Kirmison operation. He describes it in detail as he has applied it in 25 cases. In 16 the deformity was bilateral. All but 8 of the 25 children were boys. Perfect correction of the deformity is impossible, but this realizes all that at present it is possible to attain. He advises against wasting time on nonsurgical measures, as the relative correction possible to be realized grows more and more difficult with delay.

Spengler's Immune Bodies in Treatment of Tuberculosis in Children.—De los Terreros has given the I. K. treatment a thorough trial over four years in treatment of 12 children with various forms of tuberculosis. The results were good in 6; medium in 3, and the disease continued a progressive course in the other 3, 2 of the children dying. The outcome was better the earlier the stage and the older the child. The children seemed to bear the injections perfectly but it is impossible to say whether any have been absolutely cured.

Signs of Rachitis.—Juristis's further observation has confirmed his statement of three years ago that the eyes of rachitic children are rounder than normal, and show more of the sclera. This is the result of changes in the bony framework behind. He now calls attention to another sign of rachitis, from the same cause, some anomaly in the bone. The child's pubis and abdominal wall slant forward different from the normal aspect, the suspensory ligament is relaxed, and the vascular elements are hypotonic, the result being that the faccid penis sags low, straight and long.

*Expert Testimony in Murder Case. G. Fernandez Davila.—p. 168.

*Pathologic Anatomy of the Thyroid Gland. O. Heredia.—p. 177.

Iodids with Hyperthyroidism.—Delgado relates that he has obtained excellent results from the use of potassium iodid in certain cases of hyperthyroidism. Whatever the mechanism of its action, the fact of the efficacy of potassium iodid in his cases was established beyond question, and he urges others not to be withheld by their prejudices from its use with hyperthyroidism. In the especially striking case reported, the exophthalmos, tachycardia and enlargement of

the thyroid, with hallucinations and distress, had developed after a period of emotional stress and financial worry. Delgado applied psychotherapy and gave daily 4 gm. of potassium iodid, and in two days nearly all the symptoms had disappeared.

Serodiagnosis of Typhus.—Ribeyro reports that in the seven cases of typhus he has encountered, all the serums agglutinated the proteus X without exception, using a strain obtained from Paris. The range was from 1:100 to 1:10,000. Serum from guinea-pigs infected with typhus did not induce agglutination, and the tests were constantly negative with serum from nontyphus patients.

Medicolegal Report on Murder Case.—Dávila's illustrated report was completed in 1915 but he did not care to publish it before, having waited until the courts had finished with the case. The victim was General Varela, minister of war and premier of Peru at the time, shot while asleep.

*Subconjunctival Injection of Cocain. J. Santos Fernández.—p. 55.

*Some Medical Aspects of the War. F. M. Fernández.—p. 64.

Subconjunctival Injection of Cocain for Cataract and Glaucoma Operations.—Santos Fernández says that these operations can be done without subconjunctival injection of cocain, but if one wishes to omit nothing that will aid in rendering the operation a success, this is certainly to be recommended. He injects 0.005 gm. of morphin half an hour before the operation and repeats it after the operation, as it is very important to keep the patient in a tranquil frame of mind. To aid in this he does not set a day for the operation, but keeps speaking of preliminary things that have to be done, and the operation can then be performed whenever most convenient and without apprehension on the patient's part.

*Anti-Anaphylaxis and Anti-Allergy Treatment. R. Kraus.—p. 191.

*Case of Bant's Disease. E. González Cortes.—p. 212.

*Dangers of Retrograde Cholecystectomy. Vargas Salcedo.—p. 217.

Anaphylaxis, Allergy and Treatment.—Kraus reviews the history of these conceptions and of treatment based on efforts to combat the allergy. The list includes his own hetero- and auto-therapies, autoserotherapy of hemoglobinuria, horse serum in treatment of hemophilia, peptone protein therapy according to Nolf, and the use of peptone in asthma—all these are instances of the modification of the allergic processes by heterogeneous substances. Another manifestation of the same principle is the modification of leukemia and certain tumors and psychoses by intercurrent infections. Wagner's attempt to influence general paralysis with tuberculin is another effort in this line.

Technic for Cholecystectomy.—Vargas Salcedo discusses the possible dangers of retrograde cholecystectomy and tells how to avoid them. By lifting up the liver we see the triangle formed by the cystic and hepatic ducts and the right lobe of the liver. The two ducts usually run parallel here for a short distance, and a ligature thrown around the cystic duct here may by mistake include the hepatic also. In about 30 per cent. of all cases the cystic duct empties into the hepatic duct at the opposite side, at the rear or at the front, and in about 2 per cent. it slants upward to it. The arterial supply of the cystic duct is also frequently abnormal, two cystic arteries being found in about 20 per cent. For these and other reasons cited he advises to ligate the cystic duct close to the gallbladder, leaving only a stump 1 or 2 cm. long. The advantages of the retrograde technic are obvious when we have a clear view of this triangle of Budge, as we then can detect any anomalies. But if adhesions, etc., prevent ample oversight of this region, it is a blind and dangerous method. He introduces a short segment of rather hard rubber tubing in anastomosing the bile duct with the duodenum, abandoning this tube to its fate afterward. In a case reported, he inadvertently had included the hepatic duct in his ligature, and this had to be corrected at a later operation. The woman

long refused to permit this although the jaundice was intense almost from the first and became greenish by the end of six months, but there was no pruritus nor much weakness although the woman had become much emaciated. The much distended hepatic duct contained 300 gm. of bile. Recovery was smooth after anastomosis between the hepatic duct and the duodenum. The article is illustrated.

*Latent Tuberculosis in Children. J. P. Garrahan and I. Iraola.—p. 459.
The Child in the Tuberculous Family. R. Iribarne.—p. 466.
Prophylaxis of Child Abandonment. A. Tutene.—p. 469.

Classification of Gastro-Intestinal Disorders in Infants.—Berro quotes the various classifications that have been proposed by different authors, and shows their defects. His own classification separates first the breast and bottle fed. Then the disorders in the bottle fed are classed in three groups according as the food, an infection, or the constitution is involved. The constitution may show a neuropathic, spasmophilic, exudative or hemorrhagic tendency, and the food may be inadequate in quality or quantity or the food may be in excess. The disorders from overfeeding may be acute or chronic; with the acute form there is dyspepsia or intoxication, while the chronic form entails atresia, atrophy or hypotrophy. With infection there is gastro-enteritis acute, subacute or relapsing; or else there is enterocolitis, and this may be simple, dysenteriform, dysenteric or secondary. His chart thus shows the sequence and the logical indications for treatment. He concludes with an appeal for the promotion of breast nursing, saying that nothing can replace the mother's breast and the mother's heart, and reiterating that the infant has an inalienable right to its mother's breast.

Frequency of Latent Tuberculosis in Children.—Garrahan and Iraola examined 1214 children from poorer homes and in two orphan asylums at Buenos Aires, and found that 75 per cent. of the children, even though apparently healthy, responded positively to tests for tuberculosis. The proportion of positive responses was 20 per cent. less among the children who had lived all or part of their life in the asylum than among the children who lived at home.

May 17, 1919, 66, No. 3414

*Solutions of Sodium Citrate. R. Luis y Yague.—p. 393.

*Dangers of Iodin Internally. Id.—p. 394.

*Milk in Colitis. Id.—p. 394.

*Bismuth with Gastric Ulcer. Id.—p. 394.

*Diarrhea and Arsenic Treatment. Id.—p. 395.

*Causal Indicators according to the Crisis or Constitution. C. Caliera.—p. 395.

*White Swelling in Children. Alvarez Sierra.—p. 397.

*Mercurial Stomatitis, etc. Seclén.—p. 398.

*Intubation in Toledo District. C. Martín y González.—p. 399.

Preparation of Solutions of Sodium Citrate.—Luis warns that pharmacists have been known to dispense sodium bicarbonate plus citric acid instead of the sodium citrate ordered. This is particularly harmful for patients with hyperchlorhydria as it adds more acid to the stomach contents, and may explain certain failures in treatment.

Iodin Internally.—Luis has noted that iodine taken internally seems to cause gastro-intestinal disturbance in those who at some time in the past have had hyperchlorhydria or gastric ulcer. In others it induces rebellious diarrhea. Iodin has been commonly used of late as a preventive of influenza, but it is too dangerous taken internally, he declares, saying

that he knows of cases in which it was evidently responsible for gastric ulceration. It should never be given internally without investigating the gastro-intestinal past of the patient, and anything suggesting trouble of this kind, no matter how slight, contraindicates its use by the mouth. It should never be taken on an empty stomach, and the doses should be moderate and the effect supervised.

Milk in Colitis.—Luis remarks that milk is often ordered on account of the hyperchlorhydria which frequently accompanies the colitis. But it has been his experience that patients with colitis do not thrive on milk. It is liable to entail sensations of oppression, flatulence and colic, but usually without diarrhea, the tendency being toward constipation. It is better to refrain from milk in colitis, he says, but if it has to be given, there is less disturbance when it is associated with starch in the form of a gruel.

Bismuth in Treatment of Gastric Ulcer.—Luis explains the reasons for his recommendation to give the bismuth on an empty stomach. When digestion is under way and an excess of hydrochloric acid is being secreted, then it is necessary to give alkalis to neutralize this hyperchlorhydria. They should be taken at the height of digestion or at the first twinge of pain as the hydrochloric acid begins to corrode. The bismuth should always be supplemented with an alkali in this way unless we are certain that there is no excess of hydrochloric acid.

Diarrhea and Arsenic.—Luis advises supervision of the bowels when prescribing arsenic in any form or by any route. It should be given very cautiously when there is a tendency to diarrhea, and the drug should be suspended when it seems to derange intestinal functioning, especially in the debilitated. Fowler's solution seems to have the least disturbing influence of any form.

Tuberculous Arthritis of the Knee in Children.—Alvarez Sierra says that white swelling seems to be becoming increasingly common in children. As tuberculosis is constantly extending its domain, the number of cases of surgical tuberculosis is proportionately increasing and children form the largest contingent in this category. White swelling of the knee is amenable to proper treatment, but the outcome is directly proportional to the stage of the process when treatment is begun. General treatment is the main thing; the surgical measures are merely the adjuvant, he declares. Echotherapy is transcendent but it must be applied with careful technique, with brief partial exposures at first and finally of the whole body. For continuous extension, celluloid apparatus for immobilization are better than plaster. He denounces the use of the knife, saying that resection or arthrectomy only exceptionally cures a white swelling; it usually prolongs the disease indefinitely, the lesions spread, and the patient develops general tuberculosis. If the lesions are very deep and there is extensive suppuration, he advises amputation as this avoids the danger of septicemia, metastasis and amyloid degeneration of the viscera, and promptly restores the patient to his normal life. In the early stage, a medical plan of skilful intensification of the organic defense may cure, but the outcome with resection is extremely dubious. If operation is decided on, it should be an amputation and a very radical one.

February 5, 1919, 19, No. 1. Recl. Jour., 1919

*Thymus Functioning. S. Shimidzu.—p. 165.

*Tuberculous Spasms. T. Fukukura and S. Tomimaga.—p. 213.

*Arrhythmia with Beriberi. S. Kato and S. Yamaoka.—p. 229.

*Electrocardiographic Study of Action of Drugs on Heart. S. Sakai.—p. 245.

Thymus Functioning.—This is Shimidzu's second report on research on thymus functioning. He discusses here "thymus immune serum" with special regard to the reciprocal relations between the thymus and the lymph apparatus. His previous research showed that the thymus immune serum entailed atrophy of the thymus and interfered with the normal development of the animals. His further experiment have confirmed the close connection between the thymus and the lymph apparatus as a whole. He suggests that the com-

dition known as the status thymicolymphaticus may be directly traced to some early acquired injury of the thymus.

Tetragenus Sepsis.—The woman of 31 showed *Tetragenus albus* and *ovatus* in blood, joint effusion, skin and mucosa ulcerations and in the urine, but she recovered completely in two months. The first symptoms were noted three months after the birth of her first child: ulceration in mouth and in the genitals. No benefit was derived from antistreptococcus serum, but sodium salicylate seemed to hasten the recovery.

Arrhythmia with Beriberi.—In the two cases reported with diagrams by Kato and Yamada, the arrhythmia did not develop until during convalescence, as the skin symptoms were improving. The arrhythmia was of the sinusal type, and seemed to be due to vagotony.

Electrocardiographic Study of Action of Drugs on Heart.

Sakai gives a number of electric cardiograms of the surviving mammalian heart under the influence of strophanthus, digitalis, and other heart stimulants. Spartein invariably checked in all directions the functioning of the surviving heart. Caffein, theodromin and thecin all alike accelerated the pulse, but theodromin had a depressing action on the conduction of the impulse, while caffein and thecin stimulated it.

May 17, 1919, 4, No. 20

Case of Acute Infective Heart Block and Arteriosclerosis. W. C. Aalbrecht, p. 1752.

Case of Atypical Typhoid Sinus. C. L. Bouterus, p. 1741.

Echinococcus Disease in the Netherlands. A. B. van Dierck, p. 1746.

Multiple Sclerosis. H. Bolten, p. 1747.

Multiple Sclerosis. Bolten discusses the signs and symptoms of incipient multiple sclerosis as the prognosis is so important, especially at this stage. In the eight cases with an unusually early clinical picture which he reports various types are represented. In one case a healthy man of 40 fell on his knees during a fencing bout, and spastic paresis developed. By the end of the fifth month there was nystagmus, with other signs of multiple sclerosis. Bolten accepts this disease as the outcome of a congenital inferiority of the central nervous system, the same as paralysis agitans and spastic spinal paralysis. The fact that the nervous system is below standard does not become apparent until spontaneously or from some external factor, infection, trauma or emotional shock, the unstable balance is upset. The clinical picture then resulting may vary within a wide range. One young man presented for months symptoms of a brain tumor, including double optic neuritis, right deafness and right trigeminal phenomena, the reflexes abolished, but the pulse, mind and stomach were behaving normally. The progress of the case confirmed the diagnosis of multiple sclerosis although the roentgen findings still suggest a possible tumor as first cause. In another case the man of 50 had presented spastic paraparesis for ten years before other symptoms of the multiple sclerosis became apparent. One woman of 34 had a complaint of dizziness for seven years but nothing could be found to explain it. The dizziness became worse on turning the head lump down, and in the dark, and sometimes in the evening, that she lost her balance. Finally, other symptoms of multiple sclerosis cleared up the case. In the third case a man of 20 developed optic neuritis, with double vision and attacks of pain followed by briefly transient blindness. His peculiar play of symptoms kept recurring until the multiple sclerosis became apparent. One man of 20 with unmistakable multiple sclerosis for several years became suddenly totally blind. The papillae were bleached on both sides, but after a time vision returned and he recovered both eyes. The only symptoms at first in the man of 37 were homoptosis and nystagmus on the same side and scanning speech. When the paresis comes on gradually, as in the first case, a tendency to recovery can be anticipated.

Hospitalstidende, Copenhagen

June 3, 1919, 42, No. 2

Lumbar Puncture with Abscess in Brain. C. A. L. Boeck, p. 753.

Lumbar Puncture with Abscess in Brain.—Borries has found four different types of cerebrospinal fluid at lumbar puncture with suppurative cerebral and subdural processes. The fluid may be absolutely clear when the abscess is free from complications. The suppurative process may even prove fatal—from respiratory paralysis—without the lumbar fluid ever showing signs of pleocytosis. When the fluid is turbid, this indicates propagated irritation although the leptomeningitis may be minimal and not perceptible to the naked eye. The turbidity is not due to irruption of pus as the fluid may be absolutely sterile. The microscope will always reveal the leptomeningitis in such cases, but it is negligible from the clinical standpoint. Even if the patient succumbs to his cerebral lesion, the leptomeningitis may never have got beyond the microscopic phase. It is possible to distinguish between an uncomplicated diffuse leptomeningitic process in the brain by the behavior of the lumbar puncture fluid. If it retains the characteristics of a benign course, as if the meningitis were on the road to recovery, we may accept the assumption of a brain abscess free from complications. The fluid may grow less and less turbid but no one hitherto has thought of utilizing this as a means to differentiate an abscess from meningitis. This is particularly instructive when we compare the changes in the spinal fluid with the course of the case as a whole; the symptoms from the brain abscess may be growing constantly more severe while the puncture fluid is progressively clearing up. He cites several cases from the literature to show this paradoxical course, and reports a case from his own experience in addition to several he has previously published. The lumbar puncture fluid in this latest case was turbid and contained a few bacteria on the first examination but grew sterile and clearer later although cerebral symptoms persisted and necropsy revealed no macroscopic leptomeningitis. One is liable to be misled by the findings at a single lumbar puncture.

Svenska Läkaresällskapets Handlingar, Stockholm

June 30, 1919, 43, No. 2

Acute Leukemia. O. Lindholm, p. 83.

Acute Leukemia.—Lindholm's monograph on the history, clinical picture and pathologic anatomy of acute leukemia fills 255 pages, including fifteen of bibliographic references and one colored plate. Treatment is discussed in a brief paragraph to the effect that, to date, treatment can be only symptomatic. The differential points between lymphatic and myelogenous leukemia are the nuclear structure of the lymphoid cells in the blood, the oxidase reaction, and the histologic changes in the organs. The appearance of promyelocytes in the blood is no certain sign of the myelogenous type, and enlargement of the thymus is not pathognomonic of the lymphatic form. There is much to sustain the view that leukemia is an infectious disease, a sepsis, although attempts to cultivate the germ and transmit the disease have always failed to date. Abnormally high numbers of leukocytes are not a feature of the disease; there may even be leukopeny. Hence the term leukemia should be banished from scientific writings, he says. The number of leukocytes may vary widely in the same person at different times, so that there is no basis for the term "pseudoleukemia," and the term "leukemia" is misleading. Twenty cases are analyzed in minute detail (155 pages), with tabulation of the daily blood findings under sixteen headings over long periods in several of the cases.

Influenza Pneumonia in Parturients. J. Petersen, p. 1097.

Influenza Pneumonia in Parturients. Petersen's experience in twenty-three cases with a death rate of 43 per cent. confirms that reported from Germany in respect to the gravity of influenza pneumonia in labor and the puerperium. Bentzen reported in Germany a death rate of 54 per cent. and Ottow 76 per cent. Delivery usually proceeded easily and the best results were obtained in the cases in which delivery was left to nature. The period of expulsion is the most dangerous phase, and any anesthetic seems fraught with special peril in these cases.

DILATATION OF THE URETER AND RENAL PELVIS*

W. F. BRAASCH, M.D.
ROCHESTER, MINN.

Dilatation of the ureter and renal pelvis may be caused by these etiologic factors: mechanical obstruction, infection, and disturbance of innervation. The various types may be recognized by differences in (1) outline, as observed in the pyelo-ureterogram, (2) pathology, and (3) clinical data.

MECHANICAL OBSTRUCTION

Continued mechanical obstruction in any portion of the urinary tract is necessarily followed by dilatation of the portion above it. It may be conceivable that an occasional obstruction may cause urinary retention of such short duration that no dilatation in the ureter or pelvis would be apparent; but in the presence of a more or less permanent obstruction causing urinary retention, it would be impossible not to have a visible permanent distention of the ureter and the renal pelvis.

Pelvis.—Dilatation in the pelvis caused by mechanical obstruction is usually characterized by (1) predominance of dilatation in the pelvis rather than in the calices or ureter, and (2) comparative regularity of pelvic outline.

The various changes in the pelvic outline resulting from mechanical obstruction are best described by considering them according to degree. As demonstrated by the pyelogram, the following deviations from the normal pelvic outline may be noted:

1. Early hydronephrosis: (a) flattening of terminal irregularities; (b) broadening of the base of the calix; (c) increase in size of the true pelvis, and (d) shortening of papillae.

2. Moderate hydronephrosis: (a) broadening of the entire calix; (b) shortening of papillae; (c) change in the angle of insertion of the ureter; (d) increase in size of the pelvis, and (e) changes of secondary infection.

3. Large hydronephrosis: (a) partially filled calices; (b) rounded individual areas; (c) single calices; (d) diffuse outline of rounded sac, and (e) dim areas suggestive of dilated opaque fluid.

Early Hydronephrosis.—Probably the first deviation from the normal to be noted in the pyelogram with early hydronephrosis is a flattening of the terminal irregularities of the normal minor calices, together with

a slight broadening of the major calix. Immediately following or accompanying these changes may be noted an increase in the size of the true pelvis. With the increase in the size of the pelvis, a shortening or flattening of the papillae projecting between the major calices may be noted.

Moderate Hydronephrosis.—With further increase in size of the hydronephrosis, the major calix becomes considerably broader in its entire extent, as well as shorter, while the terminal irregularities will usually have been effaced. The abbreviation of the calix may proceed to such an extent that one or two irregular indentations in the otherwise rounded contour of the true pelvis may alone remain. Accompanying these changes in the outline of the calix, a marked increase in the size of the true pelvis will usually occur. The pelvic outline is usually even and well rounded along its free border; this is typical of mechanical distention. Its size now makes it easily distinguishable from a large, normal pelvis. This increase in size of the true pelvis may be out of proportion to the more moderate changes seen in the calices. With the increase in size of the true pelvis, the papillae which normally project between the major calices well into the pelvic lumen, become distinctly shorter and may become so flattened as practically to be effaced.

Large Hydronephrosis.—It will usually be difficult to demonstrate the entire contour of a greatly distended pelvis in the pyelogram because of the dilution of the injected medium by the retained fluid. The pelvis is now a large round sac, with rounded calices extending from it. The calices alone may be visible and appear as detached, irregularly rounded areas, particularly when partially filled.

The Ureter.—Dilatation of the ureter because of mechanical obstruction is characterized by an increase in the size of the lumen and by thinning of the ureteral wall. The degree of dilatation is greatest near the point of obstruction, and diminishes gradually as it nears the pelvis. This is in marked distinction to the inflammatory dilatation, which is often greatest at the ureteropelvic juncture and smaller in its lower portion. The degree of dilatation accompanying mechanical obstruction is usually greater than that resulting from infection.

A stricture of the ureter may occur which obstructs the ureteral lumen only temporarily,¹ and it is possible that the ordinary method of cystoscopic examination may fail to disclose the presence of such a stricture, when examined during the interval of patency. A ureterogram may be of considerable value in such cases and may be the only method by which the condition

can be demonstrated. Further, even though the existence of a stricture is ascertained by means of the ureteral catheter alone, its extent and the degree of dilatation above it can frequently be ascertained more accurately by means of the pyelo-ureterogram. When encountering an obstruction to the ureteral catheter, considerable difficulty may arise in differentiating between an anatomic and a pathologic condition. The catheter may meet an obstruction at any level of the ureter, as the result of some anatomic condition, such as acute angulation in the course of the ureter, marked

Fig. 1 (244137).—Gross section of ureter with chronic ureteritis. Note thickening of wall and dilatation of lumen.

elasticity of the ureteral wall, or a loose mesenteric attachment. With most anatomic obstructions, an injected fluid will pass any obstruction offered to the ureteral catheter, and the absence of dilatation or any evidence of abnormality will demonstrate the anatomic nature of the obstruction. With a pathologic obstruction, when the fluid gets by, a nodular dilatation about the obstruction or a diffuse dilatation of the ureter is visible.

INFLAMMATORY DILATATION

Any considerable degree of chronic infection involving the renal pelvis and ureter will be followed by dilatation. This dilatation is not caused by a mechanical obstruction, but is the result of either a change in the tissues, and a consequent retraction in the walls of the pelvis and ureter, or of necrosis. The dilatation may vary from scarcely recognizable irregularity of the calices or dilatation of the ureter to complete destruction of the pelvis.

The Pelvis.—Dilatation of the renal pelvis as the result of inflammatory changes in its walls differs from mechanical dilatation largely in these characteristics: (1) predominance of dilatation in the calices or ureter rather than in the true pelvis, and (2) comparative irregularity of outline. It will be found that certain renal infections (evidently those predominant in the tissues adjacent to the renal pelvis) are usually accompanied by a considerable degree of inflammatory dilatation largely in the calices, whereas, in the other renal infections (evidently those predominant in the renal parenchyma), the dilatation is confined to the ureter, with an actual decrease in the size of the pelvis. The changes more commonly found in the outline of the renal pelvis as the result of an inflammatory process are: (1) dilatation confined largely to the calices; (2) dilatation involving the entire pelvis; (3) pyonephrosis; (4) contraction of the pelvis with the dilatation of the ureter; (5) alternating contraction and dilatation, and (6) atrophy.

Dilatation Predominant in the Calices.—The earliest changes in the pelvic outline, as a result of infection, are commonly characterized by a slight broadening and irregular rounding or "clubbing" of the calices, with scarcely recognizable changes in the true pelvis. As the inflammatory process progresses, the dilatation in

the calices may become well marked, while little or no dilatation may be apparent in the true pelvis. Marked dilatation of the upper ureter, particularly at the ureteropelvic juncture, is commonly seen with dilatation in the calices.

Dilatation Involving the Entire Pelvis.—With inflammation of long duration, dilatation of the true pelvis to a variable degree, may also result. This occurs secondary to the dilatation in the calices, and is continuous with that in the ureter.

Inflammatory Contraction of the Renal Pelvis.—A decrease in the size of the pelvic outline frequently accompanies infection, which is largely confined to the renal parenchyma, involving the pelvis and ureter secondarily. The pelvis may appear markedly contracted, with narrow slits representing the calices.

Destruction of Pelvic Outline, or Pyonephrosis.—With the extension of the inflammatory process and consequent destruction of the normal outline of the calices, the cortex may be invaded, and the resulting areas of necrosis may merge with the calices. The areas of cortical destruction which extend beyond the calices may be connected by narrow isthmuses with the apexes, so as to give a very irregular outline to the pelvis.

Alternating Contraction and Dilatation.—With a chronic inflammatory process largely confined to the renal pelvis, its outline may become irregularly contracted as well as dilated. This may be due either to contraction as the result of inflammatory changes in the peripelvic tissues, or to encroachment on the lumen by inflammatory proliferation of the pelvic mucosa.

Fig. 2 (244203).—Microscopic section showing increase in size of lumen, leukocyte infiltration of submucosa and cicatricial changes in serosa. Comparative diminution of muscle fibers.

Atrophic Contraction of the Pelvis.—An atrophic condition of one or of both kidneys is occasionally observed. Microscopic examination of the renal tissue often demonstrates the existence of an etiologic inflammatory process. The resulting cicatricial changes may cause diminution in the size of the pelvis commensurate with the decrease in parenchyma.

Inflammatory dilatation of the renal pelvis frequently accompanies renal stone, and may be of diagnostic value. The typical clubbing of the calices, with little or no dilatation of the pelvis or ureter, is frequently observed. That the stone could not cause mechanical obstruction is evident from the fact that the stone may be securely lodged at the end of a calix. Such dilatation may be of definite value in interpreting the identity of a small shadow in the renal area.

The Ureter.—As with inflammatory changes in the renal pelvis, an inflammatory process in the ureter is followed by tissue changes in its walls which cause more or less dilatation. The changes in the pelvic outline may be so slight as to remain unrecognized, whereas the dilatation in the ureter may be the only evidence of a previously existing inflammatory process. The outline of the ureter, if well distended with mediums, will appear dilated as the result of infection. This dilatation is usually greatest near the ureteropelvic juncture, in contrast to the dilatation resulting from stricture of the lower ureter, which is usually greatest near the point of constriction. The ureter, particularly in its upper portion, is frequently tortuous, and occasionally appears markedly angulated.

The portion of the ureter situated in the wall of the bladder will not become dilated to the extent of the ureter above, unless the bladder itself is markedly inflamed. Dilatation of this portion of the ureter is the result of contiguous infection and is usually observed only with marked chronic infection of the bladder wall. On cystoscopic examination, no contraction of the dilated meatus may be visible, which would lead one to believe that with the alteration of tissue in the ureteral wall peristalsis is absent. Such dilatation may often be demonstrated by filling the bladder with an opaque solution and placing the patient in the Trendelenburg position, thus permitting the fluid to enter the ureter by gravity. This method will usually be found impossible unless the ureter in the wall of the bladder is dilated, since the contraction of the meatus and ureteric peristalsis would otherwise prevent the fluid from entering the ureter. Regurgitation of bladder fluid into the ureter, ascribed to insufficiency of the ureteral valve, has been noted by Hagner,² Kretschmer³ and others. Hagner surmised that this was the result of inflammatory changes in the bladder wall.

Ureteral dilatation is frequently observed with prostatic obstruction, and is usually ascribed to the result of mechanical distention. While this may be true in most cases, considerable ureteral dilatation has been observed in which the retention never was greater than approximately 50 c.c. This usually occurs in the presence of a variable degree of chronic pyelonephritis, which is evidently the etiologic factor.

Combined Inflammatory and Mechanical Dilatation.—It must, of course, be considered that both inflammatory and mechanical factors may be present with ure-

teral and pelvic dilatation. Either factor may be the primary cause of dilatation with secondary influence of the other. Thus, a primary inflammatory dilatation, such as occurs with chronic pyelonephritis, may be complicated by a stricture formation, with the usually subjective symptoms of urinary retention. Likewise, a primary stricture of the ureter will sooner or later

Fig. 4 (25012).—Microscopic section of tuberculous ureter, showing round cell infiltration of submucosa and cicatricial changes in serosa.

cause urinary infection, together with an inflammatory invasion of the ureteral wall. In fact, it may be difficult to determine which was the primary factor.

Pathology of the Inflamed Pelvis and Ureter.—The frequency with which dilatation of the ureter and pelvis is observed at necropsy, when no evidence of mechanical obstruction can be found, has been noted by various observers.⁴ With chronic infection of the pelvis and the ureter, a change takes place in their tissues which is evidently the cause of dilatation. When the pelvis is opened, the calices are usually dilated to a variable degree, and the pelvic wall is thickened. When dilatation of the true pelvis is present, it is not so great as that usually seen with mechanical obstruction to the ureter, nor is there such thinning of the walls. On inspection, the increase in size of the ureter is found to vary from a slight degree to a diameter of 2 cm. Dilatation to a greater degree than this is usually the result of mechanical obstruction. On palpation, the ureter is discovered to be thicker than normal and firmer. This is particularly so with renal tuberculosis. On cross section of the ureter, the walls are seen to be hypertrophied, and the lumen is increased in proportion. With some cases of infection, the changes found in the ureter may be greater than those visible in the pelvis. A microscopic examination of the walls of the pelvis and the ureter reveals the abnormalities: (1) proliferation and often cornification of the mucosa; (2) a variable degree of leukocytic infiltration of the submucosa and musculature; (3) a variable degree of connective change in the submucosa and serosa, and (4) a relative thickening, often to a marked degree, of the serosa. In the main, the inflammatory changes differ from the mechanical in (1) the greater degree of leukocytic infiltration; (2) in more marked corni-

nective tissue changes in the submucosa and serosa, and (3) in increase in thickness of the serosa.

Data with Renal Tuberculosis.—Of particular interest is the dilatation which may occur with renal tuberculosis. The cystoscopic picture of a gaping, dilated meatus, with marked inflammation around it, while the other meatus is quite normal in its aspect, is familiar to us all in the classical picture seen with unilateral renal

in its lower portion. With the relaxation of the bladder musculature, as frequently occurs with spinal cord disease, the ureter may relax to a proportional extent. That such a dilatation may involve the entire ureter can occasionally be demonstrated by a cysto-ureterogram.

Another form of dilatation involving the ureter and pelvis has been described by Fedorow,⁷ Israel,⁸ Bachrach,⁹ Buerger,⁹ Kretschmer³ and others, a form in which no definite etiologic factor is evident. Neither mechanical obstruction, evidence of infection nor disease of the central nervous system may be present. The ureteral meatus is gaping, the entire ureter dilated to a marked extent, and a variable degree of hydronephrosis may exist. This condition is usually bilateral, and has been variously ascribed to atony (Fedorow), spasmodic contracture of the bladder (Israel), inflammatory dilatation (Karafta-Korbutt), and congenital insufficiency of the ureteral sphincter (Bachrach). While the different authors differ widely in regard to the etiologic factor, they are all agreed in stating that no stricture can be demonstrated. We have observed five such cases at the Mayo Clinic, and the condition was bilateral in all. One of the patients died following a cysto-ureteropyelogram, the medium used being collargol. On postmortem, both ureters were found to be dilated throughout, and the kidneys were hydronephrotic. No evidence of mechanical obstruction was evident in any portion of the urinary tract, nor was there any clinical evidence of disease involving the central nervous system.

Congenital stricture is such a rarity as to be an almost negligible factor. It is probable, furthermore, that many cases of dilatation reported as due to con-

tuberculosis. The bladder in this condition is usually contracted, and the possibility of any mechanical obstruction in the urethra can usually be excluded, particularly when the condition occurs in the female. If a nephro-ureterectomy is made, the ureter is usually found with one or more strictures above the bladder wall. Occasionally, however, it may be found to be dilated throughout its entire extent, with absolutely no semblance of a constriction in any portion. The pelvis is often found to be slightly dilated; the calices to a variable degree, some very markedly, and some extending into the necrotic cortical areas. It would appear that any possibility of mechanical obstruction could be absolutely excluded, and yet we have a dilatation which remains to be accounted for. On microscopic examination, the walls of the ureter may fail to disclose any particular point of cicatricial narrowing, but will have the typical tissue changes seen with inflammatory reaction.

ATONIC DILATATION

Dilatation of the ureteral meatus, associated with paralysis of the bladder resulting from disease in the nervous system, was described by Koll.² Such a dilatation occurs with only a small proportion of so-called "cord bladders." The dilatation of the ureter is not confined to the lower end, however, but may extend to the renal pelvis. Such a dilatation may in some instances be due to backing of the urine from the over-distended bladder; atonic ureteral dilatation may be found, however, when no residual urine is present. It is more probable that the same disturbance of innervation of the bladder also affects the ureter, particularly

Fig. 6 (260776).—Typical inflammatory dilatation. Note distention of calices. Pelvis small.

genital stricture are really the result of an acquired mechanical obstruction.

CLINICAL DATA

When viewed from a clinical standpoint, the subjective data accompanying mechanical and inflammatory dilatation are quite distinct. It is difficult to conceive that there may be, without the presence of pain, an intermittent mechanical obstruction, with consequent overdistention of the pelvis and ureter by the retained urine. In the majority of cases the degree of

Fig. 7 (230063).—Inflammatory dilatation, with cortical infection characterized by a decrease in the size of the pelvis and calyces, and by a dilatation of the ureter.

pain is usually great, although it may be conceivable that with partial obstruction it might be of a moderate character. However, if it is sufficient to cause any marked degree of dilatation, the pain will necessarily be severe. With the dilatation such as is so frequently seen with chronic pyelonephritis, however, there is usually little or no pain referred to the kidney. We have repeatedly demonstrated marked dilatation, particularly of the ureter, which we regard as due to inflammatory causes, when the patient has complained of no pain whatever. In reviewing 240 cases of pyelonephritis, Thomas¹⁰ found that pain was present in less than 20 per cent. If a history of definite pain is present, we have been led to believe that there must be some complicating mechanical obstruction present.

CONCLUSIONS

1. Dilatation of the ureter and renal pelvis may occur without mechanical obstruction.
2. The differences between mechanical and inflammatory dilatation, in their anatomy and pathology and in clinical data are quite definite.
3. The clinical demonstration of inflammatory dilatation may be of diagnostic value.

ABSTRACT OF DISCUSSION

DR. GUY L. HUNNER, Baltimore: As Dr. Braasch has intimated, we differ somewhat in our views concerning the questions of inflammatory and mechanical dilatation of the ureter and kidney pelvis. I think we all agree, perhaps, as to this class that he has put under the atonic dilatations,

and we still have the question open as to what makes the dilatation in the tuberculosis cases that are dilated. It has always seemed to me that in those cases the ureter is blocked at some stage and becomes dilated, and possibly at the time of necropsy or of operation, the tissues which were blocking originally have sloughed away and have left merely the dilated inflammatory shell of the ureter. But the chief point at issue between Dr. Braasch and myself is the question of dilatation due to mechanical obstruction or to inflammation. Dr. Braasch showed slides of cases of mechanical dilatation due to ureteral stricture. I did not see any that showed the actual area of the stricture, but from the condition of the ureter I should judge that many, if not most of those cases, have a stricture in the lower end of the ureter. If you are thoroughly familiar with this work you can tell in the majority of cases by inserting an ordinary catheter or bougie, whether a person has a stricture. Sometimes I treat some of these cases of pyelitis by lavage, and it is only after wondering why the lavage does not clear up the infection, that I test out with a bulb and find that a stricture is present that is keeping up the infection and making the treatment ineffective. On the other hand, the ordinary catheter or bougie does dilate some of these strictures sufficiently so that they do clear up promptly. The men who are working in this field with the Nitze type of cystoscope will have to get some method whereby they can use some sort of a bulb, so that in getting a hang of the bulb on withdrawal they will be able to say whether the patient has stricture.

DR. HUGH H. YOUNG, Baltimore: This question is one of very great interest. It has been puzzling for many years to explain why dilatations of the ureters are seen in the roentgenogram, and very few symptoms or signs are present to explain them. Dr. Hunner has explained why some of them occur, certainly in women. There are many cases in men in which it is impossible to explain why they occur. I think there is no doubt that congenital conditions have a great deal to do with it in certain cases. We have fol-

Fig. 8 (417716).—Atonic dilatation of the ureters resulting from lesion of the central nervous system.

lowed a very interesting group of children with dilated ureters in whom we found congenital obstructions in the posterior urethra. Some of these conditions are definite diverticula, often flaplike, flaps that fill up from above and obstruct in that way, and yet can be emptied by pressure from below. They generally have a small opening by which urine can escape with difficulty, and there is a dilated urethra above, dilated and often thickened, and sometimes complete dilatation of the ureters above that. Congenital

¹⁰ Thomas, G. J.: Clinical Review of Two Hundred and Forty Cases of Nonsurgical Infection of Kidneys and Ureters, *Urol. & Cutan. Rev.* 20: 127-130 (March) 1916.

bars at the prostatic orifice undoubtedly may be the cause of dilatations of the urethra and of the kidney pelvis. I feel quite confident that many cases of pyelitis due to obstructions, are due to chronic bars, often congenital or, at any rate, occurring rather early in life and often persisting for many years. In the treatment of the pyelitis in these cases, we have used nitrate of silver, often with startling results, but most often with no results at all. Recently we have been testing out a new product brought out by the chemical laboratories of the Brady Institute. It is called "220" because that happens to be the serial number of the experiments. It is really a combination of the sodium salt of mercury and a rosin base. We have had a few cases in which we have been able to clear up renal and vesical infection with startling rapidity. In one case of chronic cystitis of four years' duration the patient was absolutely cured after three treatments.

DR. LEO BUEGER, New York: We are indebted to Dr. Braasch for having emphasized the rôle that infection plays in ureteral dilatation. However, I would like to add one thing that from the pathologic standpoint ought to receive more attention, and this concerns the pathologic processes about the kidney as well as the ureter; namely, that there are two factors, the exact nature of which we cannot estimate accurately, that are responsible for the pathologic product in ureteral lesions: first, the type of infection, and second, the peculiar reaction of the tissues in each case. In tuberculosis of the urinary tract the tissues manifest a tendency to elaborate sclerotic masses in and about the part involved, particularly when this is the ureter, but also in and about the kidney. What plays the greatest rôle in altering mechanical conditions in the urinary tract are the type of infection and this specific body reaction. Thus we encounter some types of inflammation, a very much dilated ureter with attenuated walls not of mechanical origin solely, but the result of a combination of obstructive lesions plus infection. And in other cases we find a ureter that is enormously thickened, by virtue of a peculiar kind of infection present, together with the result of the body reaction. So we see about the kidney in many cases perinephritic inflammatory processes, which produce an enormous amount of perirenal fibrosclerotic tissue. In such cases, the upper ureter is drawn toward and bound down and agglutinated to the mesial border of the kidney. A knowledge of this circumstance is of no little importance in the identification of calculus in the upper ureter when the situation seems altogether too far out (lateral) and too near the lower end of the mesial border of the kidney. Not only can we be certain of the nature of such a shadow but in the presence of a clear renal outline the existence of the pathologic ureteral displacement can be recognized at once. Conversely where no such fibrosclerosis is present the use of the shadowgraph catheter and cystoscopy will show that a shadow (calculus) in the upper ureter can be displaced mesially and can be pushed far away from the kidney toward the spine. At operation we will encounter an enormously distended ureter above the stone, no sclerotic adhesions between the kidney and the ureter and all of this can be prognosticated in advance. If we bear this fact in mind we will often be able to prognosticate dilated ureters in advance of operation and those that are sclerotic, thickened and obliterated. In

certain stages of tuberculosis we find enlarged, thickened and sclerotic ureters and more rarely we find enormously dilated, attenuated ureters. I believe that in the latter cases there is a tubercular stricture below, with a purely mechanical dilatation above. Regarding the diagnosis, I think it best for the occasional cystoscopist to abandon the much exploited method of pyelography except in rare instances, not only because it is apt to give annoying reactions and cause inflammatory processes but particularly because the routine employment of the shadowgraph catheter together with the data furnished by cystoscopy will give sufficient data to diagnose the condition of the ureter. In the presence of the dilated ureters the shadowgraph catheter will be apt to take an abnormal course, when reaching the kidney pass far out into the lumbar region into the hydronephrotic kidney. Often it will lie mesially to a stone because of the ureteral enlargement, and sometimes make a complete turn on itself so as to point downward instead of upward and even make a complete loop in the ureter when the latter is ample in capacity.

DR. ALBERT E. GOLDSTEIN, Baltimore: As to the diagnosis of stricture of the ureter in the male. Frequently, I asked Dr. Hunner why we did not see strictures of the

ureter in the male, and his answer was that we did not look for them. I agree with him. Since I have looked for ureteral strictures in the male I have found them. My method of procedure has been somewhat similar to Dr. Hunner's, that is, passing a wax bulb. I pass the wax bulb on a catheter into the urethra and then into the bladder, and then pass the cystoscope over the catheter. In this way the catheter is passed up into the ureter and on withdrawing the catheter (after the cystoscope has been removed), the hang, which Dr. Hunner refers to, is obtained if a definite stricture is present. It is not always possible to diagnose a stricture of the ureter by passing a catheter and meeting an obstruction, for the same reason that one does not always determine a stricture of the urethra by the obstruction he meets with the bougie, but on

the hang, on withdrawal, unless it is very dense. I have had a number of cases of angulation of the ureter, where the ureter was held by some aberrant vessel. These cases were seen only on pyelography or ureterography. Several of my patients have been relieved by passing a catheter into the ureter several times, and several were operated on.

In a case of painless hematuria, which I thought at first was a case of essential hematuria, I catheterized both ureters on two occasions and saw blood coming from each ureter, but following the catheterization the hematuria ceased. I did not inject silver nitrate, not being certain about the diagnosis. Whether this has any bearing on stricture of the ureter or not, I do not know. About the shadowgraph catheter, I differ with Dr. Bueger. I do not think that you can make a diagnosis of stricture of the ureter just by passing a radiographic catheter, as most true strictures have dilatations above, and it is necessary for some shadow casting substance to be used to demonstrate the dilatation. Thorium is not dangerous in proper hands. If injected properly and allowed to drain after pyelography, one should use it in every case where it is expected to find some mechanical obstruction.

DR. JOHN R. CAVELK, St. Louis: I believe we are somewhat at variance in our interpretation of just what a ureteral

Fig. 9 (8886).—Typical mechanical dilatation. Note the large size of the true pelvis in proportion to the size of the calices.

stricture is. In the paper and in the discussion we have not heard a thing about ureteral spasm. It is my impression that we must consider two types of stricture, that is, true organic stricture and the spasmodic contractions of the ureter. I see more and more of this spastic type. I have been looking for strictures, and the more I look, the fewer organic ones I find. We must take into consideration the periureteral tissues, seminal vesicles and the pelvic organs in the female. I do not believe that we can diagnose a ureteral stricture with a ureter catheter, nor do I believe that we can always diagnose a ureteral stricture with a ureterogram. We do a great deal of ureteral catheterizing, we make a great many ureterograms, and we see a lot of contractions which would lead one to believe that there was a definite stricture. You may repeat the examination and get the same finding. If you will give that individual repeated doses of atropin, a large catheter can usually be passed up the ureter without obstruction. On the contrary, the passage of a ureteral catheter through an obstruction with relief of symptoms does not mean that you have cured a patient because you dilated the stricture. In the urethra you can pass a sound during a spasm and relieve symptoms. You may have passed a catheter through the region of spasm and relaxed it. I do not want to be understood that I am doubting the presence of a ureteral, inflammatory stricture, but, aside from the tuberculous strictures of the ureter from the infiltrations from without, and those secondary to stone, I think ureteral strictures are nothing like as common as they are supposed to be. In our experimental work on ureteral ligation in animals, we found that the ureter could be tied and left so, and you have a perfect stricture, absolutely tight, sealed. At the end of a year you cannot tell which ureter had been tied. They are both open and smooth, without evidence of stricture. That is why I believe that spasm is a very important cause of ureteral obstruction.

DR. ALFRED I. FOLSOM, Dallas, Texas: The question which is most interesting to me is the difference in the explanation of the findings in these cases, whether or not these dilatations in the pelvis and in the ureter are due to an inflammatory dilatation, as Dr. Braasch calls it, or whether they are due to obstruction. I am unable to see why an inflammatory process will retract the ureteral wall. In order to retract the ureteral wall so as to give a dilatation, one must presuppose some point of support outside the ureteral wall for the retracting force, a thing difficult to understand. The only result of an inflammatory process in the ureter when it is acting alone, seems to me to be tending toward a contraction. If I understand the physiology and pathology of hollow tubes in our body, that is what it means. In other words, if we have, acting alone, an inflammatory process either in the pelvis or in the ureter, the tendency is to have that contracted and narrowed. When we find these conditions reversed, that is, when we find an actual dilatation occurring in these inflamed ureters, it means that we must find some explanation outside of the inflammation to account for it, and I believe that in the majority of these cases some type of obstruction is the real cause of the dilatation. It seems to me that we are forced to decide between these two forces. The reason why we find some inflammatory ureters that are not as dilated as others, and the reason we sometimes find ureters that are dilated in one portion and not in another, is the fact that in certain areas the contracting force due to the inflammation in the wall of the ureter is greater than the dilating force due to the obstruction lower down. And the balance of these two forces seems to me to decide and to explain the difference in the pictures we see, both in Dr. Braasch's series and in Dr. Hunner's series. We have two conflicting forces, and the balance of power as between those forces decides whether we are going to have a normal size ureter due to the preponderance of the contracting force of the inflammatory wall, or whether we are going to have a dilatation due to the fact that the hydrostatic pressure due to the back pressure, resulting from the obstruction, is greater than the inflammatory process. To me, this is the crux of the whole situation, and

I believe on that is ultimately going to depend the correct solution of this problem.

DR. W. F. BRAASCH, Rochester, Minn.: There is a difference of opinion as to the frequency with which we meet strictures in the ureter. I am under the impression that they do not occur as frequently as Dr. Hunner believes. Furthermore, it is questionable whether the "hang" of a bulb on a ureteral catheter is sufficient evidence to diagnose a stricture of the ureter. It hardly seems possible that the great variety of symptoms which have been ascribed to ureteral stricture could be cured by simple passage of a large dilating bulb. Furthermore, it is difficult to understand how a chronic stricture of the ureter can exist without causing dilatation of the renal pelvis, as Dr. Hunner claims. However, it is very probable that the existence of these wide strictures of the ureter have been overlooked in a small percentage of cases.

NEW JERSEY'S WORK IN MOSQUITO CONTROL*

WILLIAM EDGAR DARNALL, A.M., M.D.

President, Atlantic County Mosquito Extermination Commission

ATLANTIC CITY, N. J.

The "Jersey mosquito" seems to be known everywhere and has given our state an unenviable notoriety all around the world. As a matter of fact, the mosquito is no worse in New Jersey than in any other seaboard state having large areas of salt marsh land. In Connecticut, New York, and especially Long Island, Delaware, Maryland, Virginia and all the states bordering on the Atlantic seaboard, the same problem exists, and exists as acutely as it does in New Jersey; but the millions of visitors to the coast resorts of this state have been the means of our opprobrious advertisement in all corners of the globe.

Living in an era of intensive research and practical achievement, we cannot appreciate the passive attitude of accepting pests, such as the mosquito, and other health scourges without an attempt at relief when the methods of relief are practical and efficient. It is not realized that it often costs a community and the citizens of it personally much more to support a mosquito nuisance than to eliminate it.

As long as eighteen years ago, interest was started in New Jersey in the question of mosquito elimination. In 1901 an organization made up of a few public spirited citizens was formed in Orange, N. J. These men at that time had little information as to the life history, habits or varieties of mosquitoes, which is so necessary in effecting their elimination. Their work proved more or less discouraging because, in spite of money spent and work done, there were times when great hordes of mosquitoes infested the community.

About this time the late Dr. John B. Smith, the state entomologist, one of the greatest pioneers in this work, began to investigate the situation. He collected perhaps the most valuable fund of information known as to their life history, habits and varieties, and his published report will always be a superb classic and an unparalleled contribution to the knowledge of the subject. Dr. Smith created so much interest among his friends and was so successful in proving by his experiments that the elimination of this pest could be accomplished, that he finally succeeded in getting the legislature to pass an act appropriating \$350,000 for

* Read before the Section on Preventive Medicine and Public Health at the Seventeenth Annual Session of the American Medical Association, Atlantic City, N. J., June, 1919.

the work. This was to be set aside as a fund largely for experiment, a certain amount determined by the law makers to be appropriated annually. He soon demonstrated that it was no idle dream, but the work progressed so slowly that the legislature in 1912 passed an act creating commissions in each county, the funds to be raised by the assessment of from 0.25 to 0.5 mill on each dollar of the tax budget of each county.

Commissions were then appointed in the various counties, the seaboard counties being the most active in the matter. These commissions then went actively to work to solve the problem by obtaining all the known data on the subject, employing expert engineers and practical men, and forming a state organization

early presidents of the New Jersey Mosquito Extermination Association said a few years ago: "Our work in New Jersey will probably be responsible for a country-wide movement against the mosquito." These words are coming true. The outbreak of the recent war and the necessity for the protection of the health of the soldiers in the camps has brought this matter to a speedier consideration by both the public and the authorities than would have been possible otherwise, although before the war the activities of New Jersey were being felt in many other progressive communities, notably in the malarial districts of certain southern sections. However, when the time came to speed up the protection of the camps from disease, it was to New Jersey and the New Jersey Mosquito Extermination Association that the government called for help. Several of the superintendents of the county commissions of New Jersey were selected to direct and supervise the work in the various cantonnments, while the work of the Bergen County commission under the direction of their able chief inspector, Mr. J. B. Leslie, at Camp Merritt, the principal embarkation camp of the army, was a real contribution to the success of the war. The great shipyards at Hog Island and the work at League Island and Bristol were laid out under the direction and advice of New Jersey engineers and mosquito experts.

Camp Merritt, an embarkation camp situated in a malaria district, presented a situation of the utmost importance, since soldiers coming from all parts of the country might acquire infection. Among them also would be numbers of carriers of malaria brought from other states, especially the Southern states. As will be seen, the conditions would have been ripe for a continuous epidemic of malaria, which would have been carried not only to our own troops abroad but to those of all the allies. As soon as the site was chosen for Camp Merritt in 1917, the Bergen County commission made a complete survey of the territory affected and an investigation of malarial conditions then existing. It was found that while the camp stood on high ground it was almost completely surrounded by sluggish streams and overgrown swamps. *Anopheles* breeding was found along the edges of the slowly moving streams and ponds. The situation was pointed out to the commanding officer and the danger explained to him. He immediately saw the importance of it. The Public Health Service and the commission combined forces to push the work rapidly under the direction of the commission, the government supplying the labor. The work was pushed rapidly and watched carefully, and the total area controlled was about 15 square miles. The result was that during the summer of 1918, mosquitoes in and around the camp were reduced so far below the nuisance point as to be negligible; and although there were some recurrent cases of malaria among the troops coming from a distance, *there was not one case of malaria during the entire summer which originated at Camp Merritt.*

Malaria is the only mosquito-borne disease in New Jersey, and we find that in comparatively few places. There is almost none in south Jersey, but it has been troublesome at times in certain sections of the upper parts of the state. One of the most remarkable examples of what can be done, with comparatively little expense, occurred a few years ago at Princeton. The university students as well as the people of the

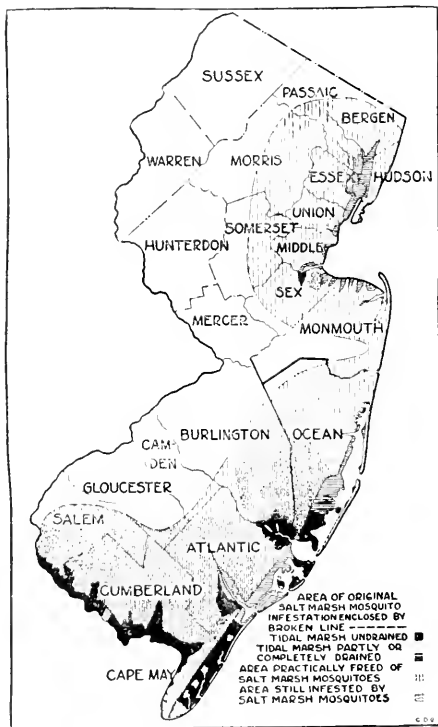

Fig. 1.—Flight of salt marsh mosquitoes inland from coast.

which meets annually to exchange views on the question. These county commissions are coordinated with the state experiment station and are under the direct supervision of the state entomologist, Dr. T. J. Headlee. The result is that the movement is organized all over the state. It is the most perfect organization, perhaps, of any large public movement in the state, and numbers several thousand enthusiasts in its membership.

"The work of New Jersey, which was the first state to take up this question," says Dr. L. O. Howard, the entomologist of the Smithsonian Institution, and perhaps the world's greatest authority on mosquitoes, "is so far ahead of every other state and every other country as to stand practically alone." One of the

village were seriously stricken with an outbreak of malaria. The low lying basins about Princeton were found on investigation to be prolific breeders of *Anopheles quadrimaculatus*, and there was much illness. The small sum of \$10,000 was raised and active and systematic work done under the direction of the state director of mosquito extermination by the local authorities. In a year's time the number of cases of malaria dropped from 257 to eight. The following year there were none. The economic importance of

one hand must look after all local types of mosquitoes, and on the other must rid the salt marshes within a radius of 40 miles from any given point by a systematic drainage system, in order to have relief.

Of the forty different species of mosquitoes found in New Jersey, practically the only ones of economic importance are the local types known as *Stegomyia*

Fig. 2.—Typical marsh pool in meadows near Atlantic City.

this result and the health importance of the protection given to a community like this with its great university is almost unmeasurable. The time allotted for this paper does not permit the mention of many cases in detail. The fact that the United States government was enabled to send millions of soldiers through Camp Merritt, situated in a naturally malarial district, without one single case of malaria occurring there, and the startling result attained at Princeton furnish brilliant and instructive examples of what can be accomplished with thorough organization, anywhere.

Certainly the vision of the pioneers of this work in New Jersey and the tremendous fund of information that has been acquired and is on record deserve our greatest respect and admiration. These men should be proud of their handiwork, which has set the standard for communities in many other states. Those who are interested in mosquito extermination in any way will find scientific and practical discussions of nearly every phase of the subject in the annual reports of the New Jersey Extermination Association for the past six years. These reports have become classics and are much sought after far and near.

All mosquito extermination must be based on the scientific knowledge of the different varieties of mosquitoes and the life history and habits of those to be dealt with in any given community. In nearly all inland places the problem is comparatively easy because it deals with what are known as local types of mosquitoes. Such types as *Anopheles* and *Stegomyia pipiens* never migrate farther than from 1 to 5 miles from the place where they are bred. Cleaning up the immediate district and organizing a good place for follow-up inspection, therefore, will quickly rid any given community of the pest, as in the case of Princeton.

Contrast now, with this, the coastal states with large areas of salt marsh meadow land breeding *Aedes sollicitans*, which has a flight under proper conditions of wind and weather of at least 40 miles. The coast counties also have the same problem of local mosquitoes as inland places, so that the authorities on the

pipiens or the house mosquito, and the malarial *Anopheles* group. The other local types are negligible. The real problem in New Jersey is to rid the state of *Aedes sollicitans*, which at times makes life miserable for nearly half of the population of the state by reason of their long flight from the seacoast, inland. Hotels will fail, summer resorts die and agricultural and industrial interests lag if unfortunate enough to be situated in districts badly infested by hungry hordes of mosquitoes. It is for this reason that New Jersey

Fig. 3.—Machine-cut ditch 10 inches wide by 30 inches deep, such as is used in all antimosquito work in Atlantic City.

has waked up to the vital importance of freeing the whole state from this menace to health and progress, and is setting the pace for other states. This community and many others in the state have been freed entirely from local and disease-bearing species of mosquitoes, but much work still remains to be done before the vast areas of marsh land will be clear.

About 16,000,000 feet of standard 10 by 30 inch ditching have already been cut on the salt marshes

in the state; about one third of this is in the county of Atlantic, representing about 1,100 miles of ditching or one third of the distance from here to Paris. There are in the state 296,000 acres of salt marsh. There still remains to be treated about 150,000 acres, so that it

Fig. 4.—Old style wooden drain holding water at all times.

may be seen that the work is about half completed. During the next five years, according to the plans now laid, this whole area will be drained and New Jersey, the home of the mosquito, can say to the world that it has no mosquitoes. Can any other state say as much by that time, especially the coast states having the same difficulties as New Jersey?

After all the work is done, the maintenance of it is of supreme importance. It is estimated from the experience already gathered that the maintenance cost per year per acre will average 35 cents. The area which has up to date enjoyed protection from the mosquito pest is 937 square miles. The population protected by this work is 2,188,063 people of the state. The per capita cost of such protection is about 15 cents.

ORGANIZATION OF A COUNTY UNIT

It might be of interest to describe the organization of a county unit, such as exists in this county and many others of the state. A commission composed of six men is invested with the responsibility of the work. A superintendent or chief inspector is the active head who, with his assistant, has full charge of the office, the various gangs of salt marsh workers and the local inspectors of the fresh water work. It is necessary for the chief inspector to be a thorough expert mosquito man and a practical executive. The work on the marshes is done by ditching machines which cut ditches 10 by 30 inches very rapidly through the marsh. Five hundred feet can be cut often in fifteen minutes, and as much as from 1,000 to 5,000 feet in a day's time. Each machine gang is under a foreman, and consists of five men. The number of feet that can be cut per day is limited only by the number of machines and machine gangs that can be employed, and that is a question of money. There are in this county, alone, about 50,000 acres of marsh land, and of this 61 per

cent., or about 37,000 acres, have been drained, leaving about 13,000 acres yet to be done. These ditches, draining into open thoroughfares and bays, allow the tides to come and go through the ditches, which are placed about 100 feet apart. As the tide recedes, the meadow land between the ditches is dried out by seepage, making mosquito breeding impossible; at the same time it allows millions of the small killifish to run up the ditches and into the pools. These fish are our most efficient allies, because they feed on the mosquito larvae. During severe flights of mosquitoes, when the undrained meadows were producing billions of mosquitoes, our patrol service has found practically no breeding on the drained and ditched meadow. That is the best test of its efficiency.

Constant patrol is given this vast stretch of marsh, and whenever breeding is found it is charted on a map in the central office so that everything the mosquito does is known at headquarters. Whenever a ditch is ineffective or clogged, all points in regard to the development of a brood of mosquitoes are charted daily, so that it can be told several days beforehand just what is going to happen, and according to the direction of the winds just what communities are going to be troubled on a certain date with an infestation, and how severe it will be.

This refers to the coast and the marshes; but the large part of this country is not on the coast, and the inland dweller is not interested in it. His problem is the fresh water or local types of mosquitoes. It is much simpler and much easier to produce almost immediate results with these varieties, because of their short migration.

The organization of this work is under the same executive head as the marsh work. Each city in this county is divided into districts. Each district is given to a local inspector whose duty it is to cover every property in his district every ten days in the mosquito

Fig. 5.—Boats open to the weather will soon raise a crop of insects.

season. The inspection of each property made for the day is recorded on a separate card and checked up at the office at the close of the day and filed. If he has found breeding on any property, this report must be on a pink card. It is his duty to eliminate such breeding as may be found in a rain barrel or a tin can, or other receptacle, and note just what and where it was.

If it is stagnant water under a house or in some other locality, it is reported, and the ditching squad or the oiling squad follows it up the next day. If the water can be drained away, it is done. If not, it must be oiled. Each pink card report filed in a separate case must be followed up in not less than ten days and

Fig. 6.—One of the beauty spots of Atlantic City. Water under such rubbish is hard to oil for mosquito elimination.

checked up. When oiling is necessary, the oiling squad must be on hand regularly every ten days to oil the surface of the water; but in reality in this community oiling is a small part of the work. As a matter of fact, after the first complete inspection at the beginning of the summer there is not much difficulty with local types of mosquitoes, except in the new conditions that may arise from week to week; and as soon as these are discovered, they are promptly eliminated. A large wall map of the city shows every spot in the city on which mosquito breeding has been eliminated for the year, and is valuable as a clue to any trouble that may arise in the future years.

By systematic organization of this sort and careful follow up work, knowing the kind of mosquito to be dealt with and his life habits and proclivities, any community with a comparatively small expenditure may rid itself of this terrible pest and enemy of health. In many communities there are engineering problems of tide gates, dikes and other methods of handling drainage besides ditching. All these may be overcome by intelligent cooperation and intensive study, and there ought to come a time when every community infested with mosquitoes will be as much under the ban as if it had the worst sanitary conditions. As a matter of fact, these two things, mosquitoes and bad sanitation, usually go hand in hand; where the one is, the other will be found.

1704 Pacific Avenue.

ABSTRACT OF DISCUSSION

DR. JUAN GUTERAS, Havana, Cuba: I would like to ask here whether any responsibility is attached to the house owners in connection with domestic mosquitoes; whether the house owner is considered responsible for mosquitoes bred in water barrels and other water containers; whether any system of fines is established and imposed on such persons.

DR. JOHN E. FERRELL, New York: I think all who have been interested in the subject of malaria control, will receive

encouragement from the paper which has been read today, indicating the feasibility of mosquito control in the very difficult areas of New Jersey. I have no doubt that those present know of the malarial control measures which have safeguarded the troops at Camp Merritt, and that they have also been carried on in all the camps throughout the country, and it is one of the greatest achievements of governmental agencies, state, federal and local, which have been entrusted with this task. You can start at Camp Merritt and go south throughout the districts where the anopheles mosquito is a menace and find that through the governmental agencies malaria has been controlled. It is important, it seems to me, having this demonstration before us, to suggest that the time has now arrived to maintain what has been obtained throughout these areas, particularly in the South, and to accept the suggestions of Dr. Darnall, and develop whatever agencies may be necessary in extending this work which has made one of the best and most successful health demonstrations we have had in connection with war work.

DR. J. D. McLEAN, Philadelphia: Pennsylvania is following on the line of New Jersey and being taught by this state in the control of the mosquito. Pennsylvania's state board of health expended last year \$99,000 for the elimination of disease breeding spots. The commissioner of health of the state feels assured that in the future his hands will be much stronger than they have been in the past, and that the mosquito breeding spots in Pennsylvania will be entirely wiped out in a very short time. The work is being continued this year and we are spending from sixty to sixty-five thousand dollars on that work. We have several just as bad breeding spots as they have in New Jersey. They are along the Delaware River, and not only in the Hog Island district. They are still farther north.

DR. JOHN P. DAVIN, New York: I am very proud as a member of this section, to hear what has been done at Camp Merritt, because I happen to have a rather intimate association with one of the gentlemen connected with that work, Edward Davin of the U. S. Army, my son.

DR. ARTHUR T. McCORMACK, Bowling Green, Ky.: I want to call the attention of the section to two practical proposi-

Fig. 7. A typical back yard on the north side. Some of these tubs were used for washing clothes, others for raising mosquitoes.

tions. In the first place, last year one of our sanitary inspectors in Panama designed a form of sectional concrete ditch bottoms of varying diameters, 30 inches long and about 4 inches thick, of reinforced cement, with a male and female end, so that the segments will fit one into the other, and by buttering these segments with green cement, it makes a tight ditch bottom. You can lay it as you lay a pavement, very

readily and very economically, and it gets rid of the problem of ditch maintenance, which is one of the greatest expenses in malarial work, because it involves a greater capital expense. I was in Panama about four and a half months before I saw any mosquitoes in the sanitarized area, and then I found two in an unused bathroom in my house. My wife telephoned to the authorities and in about fifteen minutes an automobile truck drew up with a sanitary inspector and five negro laborers from the health department in it. They went through various rooms, and after a short time located the offenders. The sanitary inspector went in with his little test tubes and he caught the mosquitoes. He examined them. It happened to be a variety I knew very little about personally. Apparently there was a hole in the screen, and so he called up the health department. They telephoned down to the proper section, and immediately a truck came with four more men, and they very carefully went over the screening, yard by yard, and found two holes large enough for these mosquitoes to come in. The screening was repaired, and we had no more trouble. In the meantime, the sanitary inspector of the health office came up with a blueprint of the entire area, because this variety of mosquito had a flight of about a mile, and on the blueprint was shown every place where mosquitoes bred. Every place was examined with a view to finding where these mosquitoes had bred. On the second day they found that just about a mile from the house was a wet spot where there had been some clogging of a drain and that little wet water stream, to use a common expression, was responsible. That drain was cleared out, and then the inspectors went to every house within half a mile and they found in two other houses a few mosquitoes. It is interesting to know how thoroughly such work can be done, and to know that that is the standard toward which we are aiming.

DR. WILLIAM E. DARNALL, Atlantic City, N. J.: In reply to Dr. Guiteras' question as to fines, we have no such system, for the reason that in the minds of the layman, the whole problem is yet considered more or less experimental. Nobody believed that anything could be done to

free a community of mosquitoes, and therefore, to put fines on people with such an uninformed state of public mind would result in the work becoming unpopular to such an extent it would be dispensed with. One of the main duties of all local inspectors is to instruct people. If mosquitoes are found on your premises and the inspectors find their source in rain barrels or other receptacles, he demonstrates the egg boats, larvae or pupae; explains how they develop into mosquitoes; empties the receptacles in order to eliminate the source of breeding, and instructs the people that it is their duty to eliminate the mosquito, and to keep stagnant water out of every receptacle. That is the way we have accomplished educational results, along, of course, with a certain amount of newspaper publicity. The result is that the whole community is interested.

Education. Every mind was made for growth, for knowledge, and in its nature is stunted against, when it is doomed to ignorance, Channing.

THE TREATMENT OF FRACTURES

SOME LESSONS OF THE WAR*

ERNEST W. HEY GROVES, M.S., F.R.C.S.

(ENGLAND)

Major R. A. M. C. (T.); Surgeon in Charge of the Special Military Surgical Hospital

BRISTOL, ENGLAND

The killing of the great war is over, but much of the curing is still to be done. Reconstruction is the order of the day and we shall do well to apply this process to the principles and practice of treating fractures, whether these be the result of gunshot wounds or of industrial accidents. There are a few good things to set against the many evil things of war, and one of them is that the number of each kind of casualty serves to magnify the details of injury together with treatment and results, so that broad principles come to be recognized which would have escaped notice if taught by only a few and scattered cases.

GENERAL PRINCIPLES IN THE TREATMENT OF FRACTURES

Administrative Principles.—It is within the knowledge of every one who has been closely interested in this question that a very marked improvement has taken place in the treatment of gunshot fractures in the last two years as compared with the first two years of the war. No doubt, experience and better technique have had their share in this, but certain administrative principles have probably had more to do with it than anything else. And it is because these very administrative principles are applicable to civil life that

they are especially deserving of consideration today.

No ingenuity of invention nor improvement in operation can compare in importance with the three principles of *segregation, continuity and team work*, as regards their good influence in both our knowledge of and good results in the treatment of broken bones.

So long as gunshot fractures were treated for one period at a base hospital in France, for a second period at a general hospital in England and for a third period at a convalescent home, the results were bad in a large majority of the cases in which function depended on skilful treatment.

FIG. 1.—Extreme adduction deformity after fracture of femur; left femur, five months after wound, treated by a Thomas splint; note states that the leg was 11½ inches shorter than its fellow. After apparent union had taken place, the deformity here figured occurred, the leg then becoming 4½ inches short.

* Read before the Section on Surgery, General and Abdominal, at the Seventieth Annual Session of the American Medical Association, Atlantic City, N. J., June, 1919.

* Because of lack of space, this article is abbreviated in THE JOURNAL. The complete article appears in the Transactions of the Section and in the author's reprints. A copy of the latter will be sent by the author or by THE JOURNAL on receipt of a stamped addressed envelope.

Reeducation.—One of the greatest advances in military surgery has been the common sense treatment of functional disabilities by reeducation or psychotherapy. By the old method, men with broken legs expected to be lame, and accordingly they invariably were lame, just so long as they were absorbed in their injury and until return to employment provided the necessary reeducation. But the new method has made a great advance over this. The bone having been kept in correct alignment and extended to proper length, the functions of the joints and muscles having been preserved, while the patient is in bed, the patient is from the very outset of his ambulant stage taught to use his leg normally and by the aid of simple instruction he quickly comes to walking well.

The keynote here, too, must be simplicity and common sense, rather than complexity and mysticism—applied early for prevention rather than late for cure of disability.

THE SPLINT TREATMENT OF FRACTURED FEMURS

The proper correction and maintenance of position of the broken bone is of the first importance. It does not constitute the whole treatment, but it is the foundation on which the whole treatment rests. The painful inadequacy of the correction of displacement in gunshot fractures of the femur in the early stages of the

falls short of this ideal in the future. In a large proportion of cases uncomplicated by loss of bone or injury to joints or nerves, we ought to be able to insure three things: full length, correct alignment and good function.

The Thomas System.—The credit for this raising of our standard belongs to one man more than any other, and that is my chief, Sir Robert Jones. He had the experience and the enthusiasm necessary to solve the material problem, and he had the faith which moves mountains of official complacency. He demonstrated that the methods of Hugh Owen Thomas could meet the essential requirements of the case and that it was particularly suitable for gunshot fractures in the field and in transport.

There are certain limitations and drawbacks of the method in which Thomas used his splint.

MODERN METHODS OF TREATMENT BY EXTENSION

These difficulties have been overcome in various ways, and it is the general opinion that better results are secured by:

Active extension by a weight and pulley. Counterextension by the body weight or by a perineal band around the sound leg.

The maintenance of the hip and knee in a position of semiflexion.

The application of the extending force by securing a direct hold on the bone by means of either transfixion or ice-tongs.

One word is necessary as to the question of the site and manner of taking hold

Fig. 2.—Outside thigh splint to prevent abduction deformity. This is applied after extension has secured correct alignment and length and after early union has occurred. It consists in a steel plate 4 by 15 inches, straight in its length and curved transversely; it is attached above to the pelvis by a wide, padded webbing which is secured from upward displacement by two perineal straps, and below to the thigh just above the condyles. It will be noted that this splint does not fix either the hip or the knee.

Fig. 4.—Diagram of fracture of upper end of femur with typical displacement.

Fig. 5.—Treatment of the fracture of Figure 4 by a long ivory or bone peg (6 by 1/2 inches). The peg is pushed upward through the great trochanter.

Fig. 6. The upper end of the peg, exposed through a buttock incision, is grasped by a metal bar, a hole in which fits over a shoulder on the peg. The bar is driven down into the shaft of the femur.

war has forced attention to the subject, and it has now been demonstrated that, even with this most difficult type of case, excellent results can be obtained both as regards structure and function, by a proper system—results which compare most favorably with those of civil practice. A high standard has been reached, and nothing will ever justify a practice which

of the bones. I have been using transfixion methods for many years and have observed both in my own cases and in those described by others that when the lower end of the thigh is pierced there occurs in a certain proportion of cases a troublesome sepsis. This is due, I believe, to the seton action of the pin and has nothing to do with the transfixion of the bone. So long

as a rod passes through the skin into the interior of the limb, there must be liability to sepsis. The danger of such sepsis lies in the fact that the track of the pin

should be met by a suitable reduction of the weight. This argument holds good only in the case of recent fractures in which the extension force has only the muscle traction to overcome. It does not apply in the case of old fractures in which fibrous or callus union has to be overcome. In all old fractures of the femur or dislocation of the hip, I use, therefore, transfixion of the femur by a $\frac{3}{16}$ inch pin and a 40 pound weight. The weight is reduced as soon as full length is reached and the pin is removed within three weeks, being then replaced by other methods; for example, plaster or tibial transfixion. But in all recent femur fractures, I use tibial transfixion with 15 pounds extension, reduced to 10 pounds within about one week.

THE VITAL PRINCIPLES OF FRACTURE REPAIR AND THEIR MECHANICAL CONTROL—THE PREVENTION OF DEFORMITY

The repair of fractures is by means of tissue which is soft at first and becomes hard only by slow degrees. Under adverse circumstances; for example, certain types of sepsis and loss of bone, the callus may remain soft for a very long period, and if a static or muscular force is constantly tending to bend the alinement, deformity will certainly result unless means are taken to prevent it. The best example of plastic callus, allowing deformity, is seen in fractures of the upper end of the femur where external angulation will inevitably occur after correct union has taken place in the absence of some external strut.

Fig. 10.—Pegging upper end of the femur. Private P., thirteen months after wounding, with ununited fracture of upper end of femur. The proximal fragment is tilted in front of the shaft.

Fig. 11.—Private P., four months after pegging. An ivory peg 6 by 12 inches was used. This peg is still in place, six months after the operation. The wound healed by first intention. Note that at both ends of the peg erosion and absorption are taking place.

passes through deep muscle and fascial planes from which either the knee joint or the thigh becomes infected. This seton action of the pin will be shared by the ice-tongs, and in many published papers a considerable incidence of sepsis is admitted with the latter appliance.

Major Pearson's contention that his caliper grasps the bone without piercing it appears to me quite incredible. The bone is often soft and atrophic and the sharp points must go through the shell of bone before they can stand the strain of a 15 pound pull.

The transfixion of the tibial crest seems to me to be the safe alternative to the transfixion of the femur. It goes through nothing but skin, fascia and bone; it needs only a $\frac{1}{8}$ inch pin; it concerns very dense bone; it can be left in place for four months, and if sepsis occurs from its seton action, it can, as a last resort, be cured by a V shaped incision of the crest of the tibia in front of the transfixion hole. It exerts traction on the thigh by pulling on the actual bony insertion of the great thigh muscles.

The two criticisms of the tibial transfixion which are fairly urged are, that it may strain the knee joint and that it interferes with the exercise of the knee.

With regard to the strain on the knee ligaments: if only sufficient weight is used to cause correct length of the leg, then this force is expended in stretching the thigh muscles, and there is no surplus to injure the knee ligaments. If more force is used than the thigh muscles require then this will be indicated by over extension of the leg and

Fig. 14.—Lieutenant T., twelve months after plating operation; there is a well marked false joint with great churning of both ends of the bone.

Fig. 15.—Lieutenant T., two weeks after the femur has been bolted by two $\frac{3}{16}$ inch bolts.

This is seen in an extreme grade in Figure 1 where a femur is shown angulated to such a degree that more than four inches shortening was produced. Such late or secondary displacement may take place as long as six or nine months after injury and several months

after union of the fracture. It is not easy to prevent this deformity by any of the ordinary appliances, for

is a difficult one, because, not only are the tissues densely tied by scar tissue, but the bone ends, especially the upper, are much atrophied and will not hold any screws.

Fig. 21.—Private X; bone graft for gap fracture of radius; gap at junction of upper and middle thirds of radius; typical loss of supination.

Fig. 22.—Private X, after bone grafting; tibial bone graft with double peg ends; lower end driven into distal fragment; upper end forced into proximal fragment after distraction. Note how the graft has restored the "loocket handle" shape to the radius.

example, a Liston's long splint of plaster of Paris, without such prolonged immobilization as will make imminent a high degree of atrophy of the muscles and fixation of the joints. A walking caliper splint will not entirely prevent it.

Provided that correct alinement has once been attained by proper extension, the adduction deformity can be prevented by the use of the outside metal splint shown in Figure 2. It is essentially a straight steel band reaching from the crest of the ilium to the condyles and attached by broad bands to the pelvis above and to the lower end of the thigh below. It can be used as an ambulatory appliance and it does not immobilize either the hip or the knee.

THE NECESSITY FOR ACTUAL APPPOSITION OF BROKEN FRAGMENTS IN ORDER TO OBTAIN UNION OF A FRACTURE

The commonest cause of nonunion of fractures, apart from gross loss of substance, is a want of contact between the fragments, either from incorrect alinement or the interposition of the soft parts. This is very common at the upper end of the femur, especially when the leg has been put up with a straight hip and knee. The short upper fragment tilts forward whilst the shaft falls back. This want of apposition is frequently overlooked at the time when it could readily be corrected, because only anteroposterior roentgenograms are used. Only a stereoscopic or lateral view shows the upper fragment is far in front of the lower.

When such an ununited fracture is presented for treatment after nine or twelve months, the problem

Fig. 23.—Private C; ununited fracture of midshaft of radius; there had been fracture of the radius with loss of about 1 inch twelve months before; the ulna had been shortened so as to bring the ends of the radius into contact.

Fig. 24. Private C, bone graft for ununited fracture of radius. The shortened atrophic ends of the bone were cut away and replaced by a tibial graft with double pegs.

cient fixation, is necessary for the successful operative treatment of fractures, and this applies in particular to fractures of old standing in which reparative tissue is very indolent.

It is the want of apprehension of these two ideas of accurate apposition and efficient fixation which accounts for many failures of plating operations and I give two examples of these in Figures 12 and 13. In

which a large gold plate has been attached by encircling strands of kangaroo tendon. Again failure resulted and nine months after removal of the plate the condition of the bone is seen. In Figure 14 is shown a case

Fig. 26.—Private T.; periosteum in fracture repair, four months after fracture of femur. The limb had been kept on a Thomas splint, three months after wounding. The sequestrums were removed, but adequate extension was not maintained. Note the festoons of periosteal callus formed by the comminuted fragments before removal.

Fig. 27.—Private Th.; periosteum in fracture repair; fractured femur; Thomas splint three months after wound; sequestrums have been removed, but extension has been maintained; sheath of external periosteal callus holding fragments in position; only $\frac{1}{2}$ inch shortening.

Fig. 28.—Lieutenant H.; periosteum in fracture repair; fractured humerus, showing the same joints as Figure 27; namely, formation of periosteal callus, when comminuted fragments were retained for a sufficient period.

the former a short plate is attached by four screws only to a fractured humerus and one of the screws does not grip any dense bone at all. There is a gap

in which a well marked false joint had formed between the densely eburnated bone ends. The sequel to this last case (Fig. 15) illustrates what I mean by an oper-

Fig. 29.—Private R.; periosteum in fracture repair, six months after fracture of femur. The limb was kept in a cast, and the fragments were held together, soon after removal.

Fig. 30.—Private R.; after three months. In central portion of bone graft and distal epiphyseal new bone.

Fig. 31.—Private R.; after nine months; almost complete reformation of the shaft of the bone after grafting.

between the bone ends and the plate serves rather to hold the bones apart than to unite them. This plate had to be removed after a sharp recrudescence of sepsis and the patient is awaiting further operation. Figure 13 shows a fracture of the shaft of the femur on to

ation which produces close apposition of newly cut bone surfaces and secure fixation. The ends of the bone were obliquely sawn and their dense substance drilled by an $\frac{1}{8}$ inch drill in many places until both cut surfaces were freely oozing blood. They were

then united by two iron bolts $\frac{3}{16}$ inch thick (as shown in Figure 15).

SOME MECHANICAL PRINCIPLES IN BONE GRAFTING

A vast quantity has been written about the vital principles of bone grafting and osteogenesis, but there is a mechanical aspect of this question which has been comparatively neglected.

These three mechanical principles; namely, extensive accurate contact of the graft to the bed; efficient fixation, and correction of the deformity, can be carried out only by very careful study and preparation for each individual patient. I have chosen a series of cases of gap fractures of the radius because they illustrate the points so well. Figures 21 to 24 show various types of this fracture, affecting the lower, middle and upper ends of the bone. For the moment, I will dwell only on the mechanical factors in the operation, reserving important matters relating to vitality for a separate section.

In the first place, then, it is essential to make a clean cut of the fragmented or withered ends of the broken bone and this should be done not according to rule and measure but until the cut surface bleeds well. The average amounts removed can be judged by comparison of Figures 21 and 22 with 23 and 24.

A graft is cut from the anterior surface including the crest of the tibia and this graft should be approximately of the same thickness as the bone which it is to replace. We are quite familiar with the fact that repair of wounds is greatly facilitated by an even contact of level surfaces. An ulcer of the leg will not epithelialize until its base is level with its edges. So with bones: if the surface of the graft lies even with that of its bed, easily and quickly do the two become one. The graft is then cut at each end, by means of a special doweling tool and file, into pegs which fit the cavities of the fragments which they are to unite. This leaves a central thick part of the graft with two peg ends. The central part must be accurately made to measure, as it determines the ultimate length of the mended bone.

The fitting of the graft into its bed may be made in various ways, the simplest being to drive one peg end into one fragment and then to slip the other fragment over the other peg-end of the graft by forcible distraction (Fig. 22). Or, one end may be driven into place and the other fitted by first splitting the corresponding bed fragment and then wiring it together (Fig. 24).

It will be noted that when this operation is complete three things have been accomplished:

1. The deformity is corrected as far as this is possible.
2. The graft is fixed in such a way that it is actually gripped by the living tissues, which in no way depends on sutures, screws or plates.
3. The continuity and the full strength of the bone is restored and then the only call for osteogenesis is to make good the line of contact.

THE PERIOSTEUM IN FRACTURE REPAIR

Faith in the periosteum as a bone maker dies very hard and many men have lost their limbs or been left with nonunion or deformity as a sacrifice to this delusion. And yet, although the evidence of the merely passive and vascular functions of the periosteum appears to us so convincing, to those who are prejudiced by the older teaching it is easily misunderstood.

In the case of a comminuted fracture of the shaft of a long bone in an adult, if all the fragments are taken out from one complete section soon after the injury, then the gap so left will be permanent, no new bone being laid down from the periosteum or thrown out by the fragments. But it will at once be protested that in many cases a gap left by the removal of fragments is often filled up well and quickly and that this is positive evidence of osteogenesis from periosteum. All such cases when examined fall under two categories: either the removal of fragments has been delayed for several weeks or months, or else the removal has only been partial, a more or less ample bridge being left across the gap. The latter kind of case is so obvious that it is hardly necessary to give special illustration of it. But the former is not so generally understood and I will give three cases in which it is well shown.

Figure 26 shows the shaft of a femur from which all the loose fragments were removed three months after the injury. Festsoms of periosteum are seen outlined by the new bone bridging the gap. Unfortunately the periosteal, or as I should prefer to call it, the epiosteal new bone, was scanty and weak in this case and deformity occurred because adequate extension was not maintained long enough.

Figures 27 and 28 are from a femur and a humerus in which the removal of the fragments was delayed for several months after injury and in each case there is enough epiosteal new bone or external callus to maintain the full length and the correct alignment of the shaft.

Contrasting now the absence of new bone in cases where a complete section has been removed soon after injury with its more or less abundant formation in Figures 26, 27 and 28, what is the explanation? Firstly, that the periosteum had nothing to do with it is shown by the fact that this membrane was equally preserved in all. But in the one case the bone fragments were removed at once and in the others they were left long enough to pour out their osteoblasts into the surrounding matrix of vascular tissues.

Whether this explanation is accepted or not, the facts are of paramount importance and lead to the conclusion that in comminuted fractures, even though septic, attached fragments must be preserved, for a time, at least, until an external callus has been laid down.

Another practical point arises in the case of a gap in a bone made by primary removal of fragments. Should extension be kept up so as to maintain full length in the hope that the gap is to be filled? Even if the above theoretical suggestions are accepted, there must always arise a doubt whether the fragments may have been sufficiently preserved to form a bridge, or left long enough to form a callus involucrem.

I think the answer to this question is a simple one. Full extension should be kept up for from four to six weeks from the date of the removal of the fragments, and then, if regeneration is taking place, it will be demonstrated, both by the roentgenogram and by the firm feeling imparted to the limb. If after six weeks there is no such evidence, then it is vain to hope for osteogenesis and the choice will have to be made between allowing the ends of the bone to come together, relaxing the extension, and waiting for an epiosteal bone graft.

THE IMPORTANCE OF THE PERIOSTEUM IN BONE
GRAFTING

It must by no means be assumed from the foregoing remarks that the periosteum is regarded as a negligible structure. In bone-grafting it is important and success may depend on its proper use.

All bone grafts, except those which are used as pegs or nails, should be cut with an ample provision of periosteum. In the series of cases illustrated by Figures 19 to 24, for example, each graft had a strip of connective tissue $2\frac{1}{2}$ inches wide, cut from the leg with the bone; of this, about half is natural tibial periosteum, and the rest, the contiguous fascia covering the tibialis anticus muscle.

This tissue is scraped off the ends which are cut into pegs. That which remains attached to the body of the graft is sewn around it so as to give it a complete envelope of its own, and the free ends are drawn like petticoats over the lines of junction between the graft and its bed.

The idea of this technic is, that the periosteum is in vascular continuity with the graft, that its wide surface rapidly establishes vascular continuity with the tissues by which it is surrounded and that it then serves quickly to act as a vascular intermediary between the graft and its bed.

Figures 30 to 34 give good evidence of the laying down of epistotal new bone by the graft and the manifestation by it of essential vitality. A complete gap of nearly 2 inches existed in the radius. A double flat graft, each part being covered by periosteum, was bolted into this gap.

Figure 32 shows the condition after three months. A copious epistotal new bone has been laid down and one of the pieces of which the graft consists shows a well marked central necrosis. Even if the new bone be regarded as an ingrowth from the bed rather than an outgrowth from the graft, the fact of the central necrosis affords incontrovertible evidence that the graft itself is alive with independent vitality. Figure 34 shows the final regeneration of this bone which gave the patient quite perfect use of his forearm and hand.

In conclusion may I summarize and link together these apparently disconnected remarks, by urging these two principles: First, that advance in the treatment of fractures is to be looked for on the lines of specialized team work, and second, that fracture repair involves mechanical as well as physiologic principles, and whether it is the education of the surgeon, the design or application of a splint, or the cutting and fitting of a bone graft, mechanics and surgery must go together, so that correct and efficient mechanism is always a part of surgical technic.

Caries of the Teeth in Denmark.—A committee was appointed by the state last year in Denmark to propose ways and means to combat caries of the teeth. The committee included a leading dentist, two physicians and the health insurance inspector. The report has just been published, and it states that scarcely 2 per cent. of the children have sound teeth, and in adults fully 40 per cent. of all the teeth are affected with caries. The report advocates propaganda to promote the care of the teeth and to teach the evils of caries, also the foundation of school and community dental clinics, and inclusion of dentistry in the provisions of health insurance. The expense was calculated at 1,500,000 kroner to start with, and 2,500,000 for annual upkeep, half of which should be assumed by the state. The report added that there might not be enough dentists to supply the demand that these provisions would create.

TREATMENT OF GUNSHOT FRACTURES *

JOSEPH A. BLAKE, M.D.

NEW YORK

The limits imposed on this paper demand the briefest statement of facts and the omission of theory.

A projectile, when producing a fracture, passes through the soft parts and strikes the bone:

1. It may then be arrested but deliver enough force to break the bone. Such fractures resemble the ordinary fracture produced by direct force. In such a case no foreign material is carried into the bone or marrow cavity, and such fractures are termed fractures by contact.

2. It may enter the bone and lodge, and produce either a hole (partial fracture) or a complete fracture with more or less shattering. Such fractures always contain foreign material. They are termed penetrating fractures.

3. It may pass through the bone and produce simply a hole or extensive shattering and comminution. In many instances, the velocity of the projectile is imparted to the fragments, which then lacerate or tear completely through the soft tissue on the opposite side of the limb. These fractures are termed perforating, and may be incomplete or complete, and may be accompanied by an extensive loss of substance. They may or may not contain foreign materials. Usually portions of the projectile remain in the wound, and frequently fragments of clothing.

On account of the differences in structure, the effects of the projectiles on the epiphyses and diaphyses differ greatly.

Because of the dense structure of the diaphyses and the violent vibration set up by the impact of the projectile, extensive fissuring and traumatism remote from the point of contact may occur, as evidenced by hemarthrosis of the contiguous articulations. On the other hand, the spongy, elastic structure of the epiphyses absorbs rather than diffuses the energy of the projectile, and consequently the lesions are generally restricted to the epiphysis itself. However, even in the case of small penetrating wounds, multiple or diffuse hemorrhagic areas may occur, leading to disseminated infection and necrosis.

It was found during the war that operation to prevent or eliminate infection was not indicated in fractures caused by rifle balls, when the wounds of entrance and exit were punctate. Operation was indicated, on the other hand, in all fractures caused by shell or grenade fragments. In fractures caused by shrapnel balls, operation was indicated only if good technic was possible, as these wounds frequently escaped infection.

NATURE OF OPERATION AND TREATMENT

In regard to the extent and nature of the operation that should be performed, the consensus of opinion at the end of the war was that it should be limited in extent to that necessary to eliminate contamination and remove actually detached fragments.

Primary and delayed primary suture of the accompanying wounds of the soft parts were successfully carried out by experienced and skillful surgeons when operating under favorable conditions, and when the wounded could be retained under their observation.

* Read before the Section on Surgery, General and Abdominal, at the Seventeenth Annual Session of the American Medical Association, Atlantic City, N. J., June, 1919.

As would be expected, the results in fractures by contact were much more favorable than in those by penetration or perforation.

When infection was present or anticipated, free dependent drainage was found to be imperative.

In regard to the transport of fractures, I shall say nothing other than that traction is absolutely necessary, and that the Thomas leg and arm splints are not only sufficient, but are also the most efficient splints for transport that we have. Every civil ambulance should be equipped with them.

In regard to definitive treatment, by which I mean the treatment until consolidation and the return of function are accomplished, that of suspension and traction by counterweights and weights acting by means of pulleys, as commenced in 1914 in my service at Neuilly, and developed later on, not only in my hospitals, but also in others in the French, English and American armies, has, I believe, been the most satisfactory and given the quickest and best results.

The application of this treatment to the arm and lower extremity will appear in greater detail in the discussion by Drs. M. K. Smith and R. T. Knight, and therefore I shall confine myself to a statement of the principles.

These principles are based on the following facts:

1. In every fracture of a long bone, the proximal fragment tends to occupy a certain position, which is determined by the muscles attached to the fragment. The forces produced by these muscles may be termed intrinsic.

2. This position, which may be designated as the position of election or rest, is readily modified up to certain limits by any slight extrinsic force, that is, one operating from without.

3. Conversely, if a slight restraint is supplied, considerable motion at the proximal articulation may occur without there being any change in the absolute position occupied by the fragment.

4. Traction on the distal fragment not only prevents overriding and shortening, but when applied in the direction of the axis of the proximal fragment, when in the position of election or rest, also tends to prevent harmful angulation at the site of the fracture as a consequence of the restraining action of the strength of the stretched muscles about the proximal fragment.

5. Proper counterbalanced suspension, by allowing the limb to follow the body, permits a considerable latitude of movement of the latter in bed without deranging the relative position of the fragments.

6. Traction, in order to accommodate itself to the position of the patient (unless the traction is contained within the splint), must be made by a weight and cord running on a pulley; and the pulley should be as far as possible from the point at which traction is made, so as not to limit the swinging of the limb.

7. The lack of fixation in permitting a certain amount of motion between the fragments does not delay union; on the contrary, consolidation appears to be more rapid, probably because of better nutrition.

8. In fractures of the humerus and femur, in both of which fixation of the proximal fragment is impossible, the limb being free to follow the movements of the trunk, no violent angulating strains occur at the site of fracture, and commencing union rapidly affords the slight restraint necessary to maintain the fragments in position.

9. With traction and suspension properly applied, it is possible to move all of the joints of the fractured limb throughout the treatment, no matter which bone is fractured.

Some of the foregoing assertions are evident, and the others have been proved by observation in the treatment of hundreds of fractures of each of the long bones.

The principles of the treatment are: to avoid actual fixation; to employ traction to its fullest possibilities in overcoming deformity, and to use suspension so as to afford the greatest freedom of movement, both of the trunk and of the joints. The chief and underlying principle is conservation of function.

The fullest application of the principles is in the treatment of fracture of the humerus, in which no splint is used and in which, consequently, there is no lateral support. The best results, moreover, have been obtained in these cases.

In fractures of the forearm and more particularly of the leg, the bars of the suspended splint afford lateral restraint; but in no case are circular bandages employed, the splint and underlying slings acting simply as a cradle.

In certain fractures of the femur, modification of the supports and of the axis of traction is necessary. For instance, in many fractures of the lower one third, the axis of traction must be lower than the axis of the proximal fragment, and a support must be applied below (that is, behind) the distal fragment.

When possible, in all fractures of the femur, skeletal traction, preferably with Ransohoff's tongs, is made directly on the lower fragment, and in some cases of fracture of the lower one third, the tongs may be used to lift the distal fragment into position by elevating the axis of traction.

The Thomas is the most useful and practical of all splints for fractures of the thigh and leg, but it must be used intelligently. For some cases the half ring modification or the Hodgen splint are preferable.

I do not believe that the best results are obtained by using the full Thomas principle of traction to the foot of the splint. Yet there is a distinct advantage, when using glued traction bands, to buckle them to the foot of the splint, and then attach the traction to the splint, or, better still, to use fractional traction on the splint. This is accomplished by attaching the traction cord to the foot of the splint and then reeving it through a pulley or pulleys on a spreader to which the traction bands are fastened. By varying the arrangement and number of pulleys, the proximal thrust of the splint may be made one half or one quarter of the entire traction on the limb.

In fractures of the upper part of the femur, unless the ring of the Thomas splint is an accurate fit and bears on the ischium, the proximal thrust of the splint will produce abduction of the proximal fragment. This cannot be overcome by a band alone, passing about the upper thigh and fastened to the inner bar of the splint, for it will simply constrict the thigh; but, as I believe Dr. Knight will demonstrate, a weight attached by a cord to the inner bar and pulling toward the opposite thigh will overcome the difficulty.

ADVANCE IN TREATMENT

It is impossible to make a statistical comparison of end-results because it has been impossible to keep more than a few patients under treatment until convales-

cence; but as far as gunshot fractures are concerned, there is no comparison possible between the results obtained at the end of the war and those obtained in the early part of the war by the old methods.

A sufficient number of ordinary civil fractures have been treated to warrant the statement that this treatment possesses similar advantages in the treatment of these fractures.

55 West Forty-Ninth Street.

STATISTICAL SUMMARY OF WAR FRACTURES*

JOHN B. WALKER, M.D.

NEW YORK

Early in 1917, in the *British Journal of Surgery*, an experienced surgeon in the British Army stated that after two and one-half years of war, surgical opinion as to the most satisfactory form of treatment for gunshot fractures was by no means unanimous. After two years' further experience, during which an enormous number of fractures have been treated by various methods, there are many surgeons who still hold divergent views. The majority of surgeons who have had a large experience with fractures have already had sufficient evidence as to the indisputable value of standard methods. As there is such a large number of surgeons who still rely on discredited methods, however, I hoped to be able to present at this meeting additional evidence (from our own records) sufficient to convince these surgeons that the standard methods—which have already given so much better results than their methods—must be used in the future. That there is need for improvement is shown by the fact that among the men examined for the last draft there were found to be 21,338 suffering from fractures with malunion; in this group were 1,110 from Ohio, 1,358 from Illinois, 1,618 from Pennsylvania, and 1,752 from New York.

HOSPITAL RECORDS

The educational value of these fracture statistics to our profession and to the public is just being taught, and when fully understood and appreciated it must improve the efficiency of our treatment. When cases of fracture are followed up, it is found that ideal functional results are not usually secured. It is only by studying the end-results that positive conclusions can be formed as to which method of treatment is the best. As nearly 60 per cent. of the fractures occurred before November 11, eight months ago, it was thought that a considerable number would have been cured and the patients discharged or restored to duty by this date, but this has not occurred. On the statistical slips for fractures which were sent to all hospitals, the answers given in reply to the question, "When can he be discharged?" were thirty days, forty, fifty, etc. Of those of whom it was stated that they would be discharged before June, less than 15 per cent. were actually discharged.

These few cases would not furnish sufficient evidence for our purpose, and, furthermore, they are not now available for study on account of the inadequate clerical force in the office of the sick and wounded; at just the time that this force should be available, it has

been reduced nearly 50 per cent. In England, the National Research Society has taken charge of all the hospital records and will classify them for the purpose of an exhaustive study. It is hoped that the War Department will take such measures as will render our valuable records available to our profession, for they will constitute a wonderful mine for research and information. As it was desired to obtain accurate data regarding all classes of fracture of long bones, a circular letter, No. 117, was sent, March 4, 1919, to all hospitals, with an inclosed blank form similar to the one used in England, France and by the American Surgical Association. This letter directed that as soon as a patient with a fracture of a long bone entered the hospital, the blank must be filled out at once by a competent officer and sent to the Division of Surgery. March 1, 1919, there were reported 5,131 fractures scattered throughout sixty-five different hospitals; 3,832 were reported as "cases in which healing has occurred or will occur without further operation and with satisfactory function." Six hundred and twenty-six were reported requiring an operation for osteomyelitis, and 673 for nonunion or malunion.

DISADVANTAGES FROM LACK OF EQUIPMENT

Many of these hospitals were not suited for the treatment of serious fractures, being neither properly equipped nor supplied with a competent, qualified personnel. In order, therefore, to afford the serious fractures of the long bones the benefit of special professional skill, the following fifteen specially equipped and qualified hospitals were designated for the treatment of fractures of the long bones—especially those of the lower extremity: Letterman; Walter Reed; Sam Houston, and General Hospitals 2, 3, 6, 10, 24, 26, 28, 29, 31, 36, 38 and 41. It was urgently recommended that all such cases, when practicable, be transferred from various non-equipped to special equipped hospitals. This request was denied and the transfer restricted to such new cases as should arrive from overseas. In the case of peripheral nerves, the request that all cases be transferred to eleven special hospitals was approved, but refused for fractures, as it was believed the average surgeon could treat them satisfactorily. Experience has demonstrated that such is not the case.

COMPLICATIONS OF OSTEOMYELITIS

Osteomyelitis has been the most serious complication of fractures, and has occurred in at least about 50 per cent. of the cases. In March, the hospital reports, signed by the chiefs of surgical service, indicated that there were 652 cases under treatment. A study of the operating reports, 55K, for March revealed the unreliability of these last figures, disclosing that there had been performed 1,606 operations for osteomyelitis. Again, in April, 740 cases were reported, although the operating rooms reported 1,535 operations. In May, there were 650 cases of osteomyelitis with 1,500 operations.

Since Jan. 1, 1919, there have been 6,921 operations for osteomyelitis. Considering the number of cases reported, these figures seemed unduly large, for it seemed as if most patients were having a series of operations. It has required much time to secure more detailed information revealing that there have been at least 2,124 patients suffering from osteomyelitis. These facts are given that surgeons may see the great difficulty that confronts one in the study of statistics unless the primary records are accurate. Several months'

* Read before the Section on Surgery, General and Abdominal, at the Seventy-third Annual Session of the American Medical Association, Atlantic City, N. J., June, 1919.

experience in the Surgeon-General's Office has shown that a very large number of otherwise competent surgeons have failed to appreciate the great value of accuracy in their records. Our records must be reliable if we are to secure real knowledge and learn from the experiences of others.

There have been reported 5,918 fractures (Table 1).

TABLE 1.—FRACTURES REPORTED*

	Femur	Tibia	Fibula	Tibia and Fibula	Humerus	Radius	Ulna	Radius and Ulna	Total
Fractures	1,214	1,121	466	632	1,258	528	375	281	5,915
Osteomyelitis	476	470	82	140	546	132	106	77	2,124

*The following statistics have been secured from the records of 1,575 femurs: right, 767; left, 737; upper third, 342; middle third, 325; and lower third, 285. Osteomyelitis, 694; not stated, 476; nonunion, 15. No shortening, 230; 1 cm., 115; 2 cm., 176; 3 cm., 128; 4 cm., 70; 5 cm., 53; and 6 cm., 78. Not stated in 686 cases.

There have been about eighty fractures in which Lane plates were applied and about 190 in which bone grafts were used. It is believed these numbers will be increased when more records are received.

MORTALITY, HEMORRHAGE AND AMPUTATION

The records for mortality, secondary hemorrhage and amputation are very incomplete. In this connection it may be well to quote the British records for 1914, 1915 and 1916. Four per cent. of the patients died in the field and 16 per cent. in casualty clearing stations, making 20 per cent. at the front; the mortality at the base hospitals in France and England was approximately 20 per cent., giving a total of 40 per cent. During 1917 and 1918, as a result of many improvements, this rate was reduced to less than 20 per cent. The statistics of Great Britain and the United States given in Table 2 are interesting.

TABLE 2.—EYESIGHT, HEAD, AND AMPUTATION CASES RELATING TO FRACTURES: STATISTICAL DATA OF GREAT BRITAIN AND THE UNITED STATES

	Great Britain		United States	
	No.	Per Cent.	No.	Per Cent.
Eyesight cases	11,547	2.6	2,090	1.9
Wounds and injuries to legs necessitating amputation	13,585	2.7	746	1.1
Wounds and injuries to arms necessitating amputation	6,400	1.1	1,868	3.6
Wounds and injuries to legs not necessitating amputation	50,491	12.0	8,497	16.0
Wounds and injuries to arms not necessitating amputation	13,055	8.8	3,037	6.9
Wounds and injuries to hands not necessitating amputation	20,616	4.3	1,994	2.7
Wounds and injuries to head	10,270	3.9	576	1.1

It is too early to give the end-results of fracture treatment. However, it may be useful to record some general impressions gained by observation at hospitals in France, England and United States.

TYPES OF SPLINTS

For transport of the patient from the field to the evacuation hospital or base hospital, the Thomas or Blake-Keller modification is unquestionably the best type of splint.

During the period of infection, for the lower extremity, the Thomas or Hodgen splint used with the Balkan frame, with extension by suspension and traction, has given the best results. For many fractures of the lower third of the femur, with backward displacement of the upper end of the lower fragment, no type of splint has proved so generally efficient as the caliper. In Germany, during 1914, 1915 and 1916 the Steinman

pin was used extensively, more so than by the French or English. During 1917 and 1918 there has been a great increase everywhere in the use of the caliper.

For the humerus and the elbow, the Thomas arm splint suspended from a Balkan frame with efficient extension has been most satisfactory. In some cases the aeroplane splint is much more comfortable.

In very many cases in which the Thomas splint was employed, it was not properly applied, the so-called extension straps were very rarely found to be tight enough. These straps should be examined daily and kept constantly taut.

CAUSES OF POOR END-RESULTS

In a large majority of the hospitals measurements have been neglected. Seldom has a tape measure been accessible, and in 35 per cent. of the cases there has been no statement of any measurements. Tape measures are as essential as are thermometers. In those hospitals in which measurements have been omitted, the largest number of cases of marked shortening have occurred.

Röntgenograms have not been taken regularly, although the roentgenographic departments have been well equipped with apparatus and personnel, ready to cooperate with the surgeon. Many of the poor end-results have been due not to a lack of knowledge but to neglect to carry out in detail well recognized methods of treatment.

The average general surgeon has failed to devote the attention and consideration to the treatment of fractures which this important subject demands. The results obtained previously by inefficient methods are unsatisfactory, the young, able, alert surgeons who have had a good hospital experience will be given much of this important work in the future. There will be splendid opportunities in the great manufacturing industries, public service institutions, power plants and railroads.

BONE FISTULAS AFTER WAR WOUNDS*

PEDRO CHUTRO

Buenos Aires

The word "osteomyelitis," employed to designate the suppuration of bone after war wounds, seems to me incorrect; we should reserve this name for the very definite disease which we see in civil practice, and designate simply as "bone fistulas," the chronic suppurations of the bones resulting from a war wound.

The term osteomyelitis implies in itself an early treatment consisting in the incision of the periosteum, followed by the trephining of the bone, and the opening of a seat of infection to prevent its propagation; in the wounds of war, all this operation has been done by the projectile, and what one is to treat is a localized lesion with characteristics entirely different from those of true osteomyelitis. The term "bone fistula" is more proper to designate this obstinate lesion, which more resembles an infirmity than a disease.

Granted that the lesions of bone following war wounds are not the same as those of the osteomyelitis of civil practice, neither can their treatment be the same.

* Read before the Section on Surgery, General and Abdominal, at the Seventeenth Annual Session of the American Medical Association, Atlantic City, N. J., June, 1919.

CAUSES OF BONE FISTULA

Before explaining the general lines of treatment of bone fistulas, I will permit myself certain considerations as to the origin and the pathologic anatomy.

The bone fistula is established always as a consequence of an insufficient treatment of wounds, whether it be because one has performed an incomplete operation leaving metallic foreign bodies, fragments of clothing, or bone fragments which are transformed later into sequestrums, or whether one has not been able thoroughly to clean the wound, or has not been able to take the necessary steps to avoid secondary infection. The anatomic lesion is simply a limited osteitis, which easily becomes chronic.

It seems useless to me to speak today of the treatment of the wounds and of the means of avoiding fistulas; the important thing is to know how to treat them.

Certain rare cases heal after the extraction of the foreign bodies and the sequestrums overlooked at the primary operation; but the time elapsed since the armistice leaves little hope for these cures. Most of the cases of bone fistula have already, at this date, undergone several operations, and it is rare, today, to find foreign bodies or, perhaps, even sequestrums.

Among several hundred cases of bone fistulas which I have had occasion to treat, I have seen only certain rare instances in which the suppuration proceeded from a focus of infection in the external surface of the bone; the great majority presented a focus in the interior of the bone or of the callus, except in cases of the cranium and the scapula.

Two factors dominate all the process of the bone fistula: first, the presence of a cavity with rigid walls; second, the infection of this cavity.

Some examples of these cases will avoid a long description. A shell fragment entering the tibia causes a loss of substance which, after esquillectomy, extraction of the projectile and cleaning, will take the form of a real cavity in the interior of the bone. If the projectile has gone through the bone, one will have instead of a cavity a veritable tunnel, whose bony walls will never approximate. The mildest infection will suffice to create a focus of osteitis in this cavity or in this tunnel, realizing the conditions necessary for the establishment of a fistula.

Another type, very frequent in the wounds of the leg, is: fracture of the bones by a shell fragment; tearing of the interosseous membrane; esquillectomy; infection; suppuration; consolidation with a great callus which unites the four fragments, invading the interosseous space and having in its middle a bony cavity containing sequestrums, fungosities, etc.

In the femur the condition is observed still more frequently and may be given in outline here as: fracture by a shell fragment; esquillectomy; immobilization in an apparatus which generally does not cause coaptation of the fragments, and does not prevent the displacement backward of the inferior fragment; formation of a voluminous peripheral callus, with separation of the two bony extremities within its interior by a quantity of interposed tissue; some sequestrums, and a cavity, suppurating, full of fungosities.

To summarize, it is the cavity and the infection of the cavity which dominate the process, the one being essential to the other, and the removal of only one of these factors is not sufficient to obtain healing.

CAVITIES AND FUNGOSITIES

Again, in the body, every real cavity must have a communication with the exterior, and the fistula is in reality only the exit of these bone cavities.

This said, it remains for us to observe certain peculiarities of these cavities. Bone is a specialized tissue whose evolution is terminated, and which by itself is incapable of furnishing bone to fill the cavity. It is equally incapable of giving healthy granulations; unhealthy bone only produces fungosities. These fungosities are the product of the infection of the wall of the suppurating cavity, which provokes the necrosis of little bony lamellae, around each of which grows a granulation. Sometimes these fungosities are flat and only line the wall of the bony cavity; in other cases they are exuberant and apparently fill all the cavity; but it is always easy to pass a probe between the fungosities and to feel denuded bone in the depth.

Some cases come to eliminate all the little sequestrums, and after months or years the fungosities sclerose, giving a cure of variable duration; more frequently this spontaneous cure does not take place. Bone is a tissue which defends itself poorly against infection, and once infected it reacts in a peculiar manner, seeking to limit the process by the formation of new bone around the focus, that is to say, by establishing a veritable blockade around the infected zone, but without succeeding in cicatrizing the lesion.

For a long time we have sought to establish the degree of depth of the infection of bone, and we have arrived at the conclusion that the infection is very superficial. This fact is as valuable for cases in which the patients have undergone one or two operations as for those who have undergone twenty.

The bacterial flora is of the richest, and one finds all the aerobic and anaerobic organisms which inhabit these cavities communicating with the exterior.

BONE FISTULA DISTINGUISHED FROM OSTEOMYELITIS

This lesion is entirely different from the ordinary osteomyelitis which commences by an infection in the metaphysis; and it follows its evolution, whether toward the periosteum through the haversian canals, or toward the marrow cavity through the spongy tissue.

Cases of bony fistula present little of the phenomena of infection because the cavity, communicating with the exterior, has little retention. Again, all the lymphatics around the focus are blocked, and in consequence there is no absorption of the septic products; but a slight intervention, a dressing made a little awkwardly, suffices to abolish this lymphatic blockade, and one sees immediately the appearance of fever and of the phenomena of intoxication by absorption of septic products.

TREATMENT

The treatment of bone fistulas is variable, from a technical point of view, according to the bone involved, and in each bone, according to whether the lesion is located in the diaphysis or in the epiphysis. But in spite of the variety of the treatment, it always obeys the general principles which I shall endeavor to set forth in an exact manner.

In the first place, it is necessary to place the incisions in appropriate regions, even disregarding the site of the fistula, in order to avoid certain difficulties later. Thus, a straight incision on the anterolateral aspect of the tibia causes a retraction of the skin which will retard cicatrization enormously. An incision placed

on the anterior aspect of the thigh will give rise to serious functional trouble on the part of the quadriceps; and, if the wound heals, there will remain a deeply depressed scar, adherent to the bone, which easily ulcerates. The incision placed behind the trochanter causes difficulty in the function of the gluteus, and sometimes phenomena of compression of the sciatic. The same is true for the upper extremity.

The intervention with the bone will consist in the suppression of the bony cavity, the principal cause of the fistula. To effect the intervention, it is necessary completely to resect one of the walls of the cavity and, by preference, that which is located far from important structures such as the nerves, but near muscular masses. There will remain only half of the bony cavity in the form of a simple depression; that part which is infected will be relieved of its fungosities and its sequestrums by a curettage, gentle but careful.

The operation is finished by details proper to each segment of the limb, which will be described in chapters of surgical technique.

The cicatrization of bone is brought about by granulations, but the granulations will not come from the bone; they will come from the depth toward the periphery, and will grow from the neighboring muscles. These granulations will little by little cover the vivified surface of the bone, until they cover it entirely, and from that moment the healing of the lesion is assured.

To arrive at this result, it is necessary that the vivified surface of the bone be maintained sterile during several weeks, that is to say, during the time necessary for the granulation. It is here that the treatment of Carrel-Dakin finds its application. The abundant and prolonged irrigation of the wound during several weeks permits it to be maintained clean.

We do, therefore, the contrary of that which others have done, that is, instead of seeking to sterilize the wound before interfering, we do the first operation and then we irrigate to maintain the result of the operation and to favor healing. If the operation has not been satisfactory, the irrigation does not augment the chances of cure.

We never employ the Esmarch bandage. We secure most careful hemostasis of the soft parts, and we commence the irrigation immediately after the operation.

We do not tampon, because a compress left for twenty-four hours is the best medium for the reinfestation of the bone which has just been cleaned. Infection of bone takes place in a few hours.

The tibia, so accessible to the sight, has permitted us to study the different phases of the cicatrization. Certain cases in which the wounds were not irrigated until several hours after the operation presented later little bony surfaces refusing to receive the granulations coming from the muscles, and we arrived at the following interpretation: A clot having adhered to the bone, the Dakin solution maintained sterile the surface of the clot, but not the part of the bone to which the clot adhered. We have found that the fluid commences to act when the clot has been detached, that is to say, at the end of five or six days, when the bony surface has been partly infected. That is the reason for which we commence the irrigation immediately.

When the bony surface is completely covered by granulations, one can close the wound secondarily; but

this procedure does not present great advantages, and it has, rather, some disadvantages. In fact, the scar adheres too closely to the bone, and this has no pad of protection. We prefer to continue the irrigation until complete healing is accomplished, with the aim of obtaining a cicatrix that is more supple, and especially to have a greater quantity of connective tissue separating the skin from the bone.

When the wound is healed, we perform, under local anesthesia, the complete removal of the cutaneous scar and the most complete reconstruction possible of all the anatomic planes.

After many attempts, we have come to establish different types of operations which have permitted us to obtain very satisfactory results. We have operated on several hundreds of these fistulas. The first cases were failures; but in the last series of 329 cases, all the wounds of the humerus have healed, as have also wounds of the ilium; five femurs and three tibias have not healed.

All the patients, before entering Buffon, had already been operated on between four and twenty-three times, and treated with the whole series of antiseptics and pastes that have been invented during the war.

ABSTRACT OF DISCUSSION

ON PAPERS OF DRs. GROVES, BLAKE, WALKER
AND CHUTRO

DR. JOSEPH R. EASTMAN, Indianapolis: One can, as a rule, by the external use of metal splints accomplish all that is attained by the employment of the somewhat complex devices presented. A Thomas metal splint with a knee joint in it and with a catch which will prevent hyperextension of the knee can be so applied as to allow of passive movement of the knee joint and at the same time provide extension and counterextension. With such a modified Thomas splint the entire lower extremity can be supported precisely and securely with straps of rubber or flannel so that lateral, longitudinal or angular displacement is corrected and alignment of the fragments is attained in nearly every instance. Such a knee joint Thomas splint allows of movement of the patient in bed, from one bed to another and admits of ambulant treatment of the fracture with so little inconvenience that one surgeon can take care of many patients. A long screw at the foot regulates the degree of extension. The ring at the upper end of the splint is attached to short bars which slide on the long internal and external bars of the splint so that the ring may be turned half way around and applied either to the left or the right lower extremity. The arm sling of Robert Jones, of Liverpool, is an almost ideal device for the treatment of gunshot fractures of the humerus or forearm. With it one can secure any degree of extension of the arm and forearm. I have modified this splint somewhat by adding a ratchet device which allows of any degree of abduction of the humerus; a point of some importance, since if ankylosis occurs at the shoulder joint the greatest arc of mobility is secured, if the ankylosis occurs with the humerus in abduction. The arm and forearm rest on a right angle wire splint supported by a wire brace which moves at the free end on the ratchet of a rectangular wire frame resting on the side of the chest with a ring surrounding the shoulder at the upper end. If there is great difficulty in keeping bone fragments in alignment in a case of compound fracture with great laceration, I can see no harm in laying on a Lane plate with the understanding that the plate is to be taken off. In war fractures there is often such laceration of the soft parts that no incision is necessary and the plate is applied with the greatest ease. After a few weeks when the soft tissues have become "set" the plate is easily removed and though there be no union, alignment has been established and is thereafter easily maintained, which it would have been difficult to accomplish otherwise. Extension and counterextension are then sufficient to

hold the fragments in place while bony union is being established. Of course, in an infected fracture the intramedullary bone graft cannot be used and external splints may fail to maintain alignment. It should be remembered that the Lane plate can be removed with the greatest ease if infection should require the removal of the internal splint, whereas, it is difficult to remove an intramedullary bone peg. Too great caution cannot be observed in the use of bone pegs following war fractures, since even months may elapse after complete external healing has occurred and yet the trauma incident to an open operation will reawaken a dormant infection. Hence the prudence of relying on osteotomy with extension and counterextension more often than is common practice in the correction of old badly healed war fractures. I have used the Groves wire cradle splint for fractures of the femur many times. I do not believe there is a better femur fracture splint for use in war or civil practice. It might be described as a Hodgkin splint supported below by posts instead of being suspended from above. The surgeon can work over or under it. It admits of easy access to every part of the leg or thigh while extension is being carried on. When the Steinmann pin or any sort of ice tong device is used this wire cradle splint is especially satisfactory. The weight and pulley are attached to the splint itself, maintaining pull in any direction with mathematical accuracy. I believe the Groves cradle splint to be one of the most valuable developments of war surgery.

DR. MORRIS K. SMITH, New York: The treatment of gunshot fractures of the humerus, as carried out on the service of Colonel Blake at the American Red Cross Military Hospital No. 2 in Paris, permits the maintenance of joint and muscle function. Points which I wish to emphasize particularly are: (1) the method permits of control by the surgeon of the position of the fragments; (2) union takes place rapidly; (3) disability is reduced to a minimum by mobilization of joints and exercise of muscles. Records are particularly difficult to keep under the condition of active war surgery. However, in the case of fifteen American patients the time of beginning union was noted averaging twenty-four days, and in twenty-six the time of consolidation averaged forty days. As our patients were, in general, evacuated early, we are unable to give much data as to the time of functional cure. We have treated a small number of simple fractures by this method and they have done excellently.

DR. RALPH T. KNIGHT, Minneapolis: The interesting part about the treatment of war fractures is that the principles have been and will be used extensively in fractures of civil practice. The point I wish to call especial attention to is the possibility and importance of mobilization of the knee joint during the treatment of all fractures of the femur and the bones of the lower leg. It has been shown conclusively and consistently by Colonel Blake that it is not necessary to immobilize the fragments completely in order to obtain the nearest union and return of function; and it is possible to obtain sufficient immobilization of fragments still leaving the knee free to be moved by the patient with proper apparatus.

Practice with Sickness Insurance in Germany. The *Norddeutsches Lloyd* states that a regulation has been adopted by the sickness insurance companies at Hamburg—mainly through the efforts of Professor Pfeiffer—which he thinks should be imitated by the companies throughout the whole country. The insured pay as their premiums 4 per cent. of their wages. Of the amounts thus paid in, the companies pay out 23 per cent. for medical care, the house physicians receiving three-fourths of the whole and specialists one-fourth. For any extra attendance at night or in emergencies physicians not under contract with the company are to be called on. The payments are to be according to the work done and this is estimated by a commission composed of physicians and representatives of the business office of the companies. The insured have free choice among the physicians under contract with the company. The agreement is to be in force for two years. The details were given in the *Monchener med. inische Wochenschrift*, No. 29.

AMERICAN-MADE SYNTHETIC DRUGS—II

EXAMINATION OF PROCAIN (NOVOCAIN), BARBITAL (VERONAL), PHENETIDYL ACETPHENETIDIN (HOLOCAIN), CINCHOPHIX OR PHENYL CINCHONIN ACID (ATOPHAN), MANUFACTURED UNDER FEDERAL TRADE COMMISSION LICENSES*

PAUL NICHOLAS LEECH, Ph.D.

WILLIAM RABAK, Ph.G., Sc.B.

AND

A. H. CLARK, Ph.G., Sc.B.

CHICAGO

Before European hostilities, the United States was so dependent on Germany for synthetic drugs that the dependence was considered a necessity; this was strikingly manifested by the precipitous rise in prices immediately after the embargo was declared against Germany. Since then the shortage of German-made synthetics has caused two important results: 1. The physician can do without most of the German drugs, because the pre-war demand had been stimulated artificially. 2. Those few synthetics, which were in great need, are being rapidly replaced by the American-made drugs.¹ In connection with the second result, the Chemical Laboratory of the American Medical Association has endeavored to contribute its services.

In September, 1917, it was announced² that the A. M. A. Chemical Laboratory would make studies of American-made synthetics. Just prior to this announcement, the National Research Council established a committee on synthetic drugs³ "to facilitate the manufacture of synthetic drugs in this country and thus to relieve shortage and reduce the exorbitant prices which have resulted from the war."⁴ Also during this time Congress was considering the "trading with enemy" act, first known as the Adamson bill—the purpose of which was to confer authority on the President to license American firms to use U. S. patents owned by German subjects. The act became law, September 28; the Federal Trade Commission was designated by the President to carry out the provisions of the law as it referred to enemy-owned patents. As a result of a conference, Oct. 30, 1917,⁵ with various agencies, the Federal Trade Commission decided to consider licenses for manufacturers of synthetic drugs, after recommendations had been made by the Committee on Synthetic Drugs of the National Research Council; this committee in turn invoked the aid of the A. M. A. Chemical Laboratory in testing the manufacturer's products. The essence of the laboratory's work up to July 1, 1919, is reported in this paper.

THE NAMING OF LICENSED DRUGS

"Partly in order to help insure to licensees a market for their products after the war, in larger part inspired by the idea of encouraging the establishment of a permanent American industry in these important articles, the [Federal Trade] Commission wisely decided that American houses should be put on the same footing as competing foreign houses for after-the-war competition, by imposing on all licensees the obligation to use *new official names* for the articles, names which after the war will be open to all competitors, domestic and foreign."⁶

The new American names are:

Arsphenamin,⁷ (contracted from the scientific name arsephenolamin) for salvarsan, arsenobenzol, diarsanol, arsaminal.

Barbital (contracted from the scientific name diethyl-barbituric acid) for veronal.

Barbital-sodium (the sodium salt of barbital) for "veronal-sodium" and "medinal."

Cinchophen for atophan or phenyleinchoninic acid (the U. S. P. IX name).

Procain for novocain hydrochlorid (from "pro" and "(co)caine").

Procain nitrate for novocain nitrate.

EXAMINATION OF SYNTHETIC DRUGS

In testing chemically the products which had been submitted to the Federal Trade Commission, the aims were that the product should conform to a high degree of purity; at the same time the candidate for license should not be inflicted with undue hardships in making the product, such as an unnecessarily high degree of purity. It was insisted that the purity of the drugs should be equal to, if not greater than, that of the respective former German-made products, in order to uphold the name and reputation of the American manufacturers in the after-the-war competition. Consequently, in the chemical work the American product was always examined parallel with the German-made product, authentic samples of the latter of which the laboratory had in its possession. Whenever possible, the tests described in books of standards were carried out.

BARBITAL (VERONAL)

Barbital was introduced into medicine under the proprietary name "veronal," and was manufactured in Germany by Friedr. Bayer & Co., Leverkusen, and E. Merck & Co., Darmstadt, Germany. Barbital is described in New and Nonofficial Remedies 1919⁸ as diethylbarbituric acid (diethylmalonyl urea).

It is official in the British Pharmacopoeia under the name "barbitone," and in the German Pharmacopoeia as "acidum diethylbarbituricum." Barbital "may be prepared by the interaction of esters of diethylmalonic

acid with urea in the presence of metallic alcoholates. . . . It is also obtained by condensation of diethylcyanacetic ester with urea by means of sodium alcoholate." Barbital is used in medicine chiefly as a hypnotic.

The different brands of barbital which were submitted to the laboratory were subjected to the tests given in the books referred to above.⁹ The products were:

1. Barbital (Abbott) Sample A, to Federal Trade Commission.

2. Barbital (Abbott) Sample B, to Federal Trade Commission.

3. Barbital (Abbott) Sample C, to Red Cross.

4. Barbital (Antoine Chiris), to Federal Trade Commission.

5. Barbital (V. Halter), to Federal Trade Commission.

6. Barbital (Rector Chemical Company) to Federal Trade Commission.

7. Diethylbarbituric acid (Merck), to Council.

8. "Veronal," manufactured by Farb. vorm. Friedr. Bayer & Co., Germany.

All responded satisfactorily to the tests. In Table I are given the respective melting points and percentages of ash found. (The melting point of a mixture of the sample with the original "veronal" was always taken.)

TABLE I. MELTING POINT

	Ash		Ash
1.	188.5 189.0	5.	188.0 188.5
2.	188.5 189.0	6.	188.0 188.5
3.	188.0 188.5	7.	188.0 188.5
4.	188.0 188.5	8.	188.0 188.5

Barbital does not seem to form an insoluble salt with chlorplatinic acid; nor an ether-insoluble hydrochlorid or oxalate; nor an insoluble barium salt. It does not respond to many urea tests, and is not affected by urease as would be expected in light of the extensive investigations made on this enzyme by Van Slyke and Cullen.

As barbital is also sold in the form of tablets or mixtures, a reliable method for its quantitative determination in the presence of other substances is needed. Some experiments in this direction were made, but the press of other work did not permit their continuation. When time permits, this work will be resumed.

At the time of writing this article, licenses for manufacture had been granted by the Federal Trade Commission to the Abbott Laboratories, to Antoine Chiris Company, and to the Rector Chemical Company.

BARBITAL SODIUM (MEDINAL OR VERONAL-SODIUM)

Barbital sodium, formerly sold under the proprietary names "veronal-sodium" and "medinal," is, as the former name suggests, the sodium salt of diethylbarbituric acid. Its therapeutic advantages are stated to be that more rapid results are obtained because of its increased solubility over barbital alone.¹⁰ Barbital sodium should yield, according to theory, 11.19 per cent. of sodium and 89.81 per cent. of diethylbarbituric acid. A number of years ago, when "veronal-sodium" and "medinal" were being introduced, Puckner and

7. The testing and standardizing of arsephenamin is being done by the Hygienic Laboratory, U. S. Public Health Service. For chemical tests see reprint 472, *Public Health Reports*. For a review of the patent literature see article by H. F. Lewis, *J. Indst. Engin. Chem.*, Feb. 1, 1919, p. 141.

8. New and Nonofficial Remedies, 1919, published by The Council on Pharmacy and Chemistry of the American Medical Association, p. 82.

9. The pharmacopoeia monograph on barbital has been omitted. It was published in the 1918 edition of the Annual Reports of the Chemical Laboratory of the American Medical Association.

10. New and Nonofficial Remedies, 1918, p. 96.

Hilpert¹¹ found that these products yielded results corresponding closely to the theoretical amounts of sodium and diethylbarbituric acid. A recent examination of veronal-sodium, Merck, made for the Council on Pharmacy and Chemistry, showed it to be of the same composition as that previously reported.

Only one firm's product has been submitted to the laboratory through the Committee on Synthetic Drugs,

TABLE 2.—EXTRACTION OF A SAMPLE OF BARBITAL SODIUM

	Length of Time	Diethylbarbituric Acid per Cent.
a.	Immediately	75.5
a ^b .	7 1/2 hours	82.0
b.	Immediately	82.0
c.	1 1/2 hours	80.5
d.	2 hours	82.82
e.	4 hours	82.56

h.	4 1/2 hours	84.73
Theory		89.21
Veronal Sodium (Puckner and Hilpert)		89.01 (average)
Medinal		88.97 (average)

but because of the unsatisfactory results, it was not recommended for license, nor, as far as we are aware, has the firm investigated its anomalies.¹² The amount of moisture in this specimen was 0.04 per cent. It yielded 10.94 and 10.97 per cent. of sodium. Puckner

ethenyl-paradiethoxy-diphenyl-amidin hydrochlorid $\text{CH}_2(\text{NC}_6\text{H}_4\text{OC}_2\text{H}_5)(\text{NH}_2\text{C}_6\text{H}_4\text{OC}_2\text{H}_5)\text{HCl}$. It is used as a local anesthetic for the eye.

The standards, such as had been described, were meager and unsatisfactory. Hence when the first specimen of American-made phenetidyl-acetphenetidin was sent to the A. M. A. Chemical Laboratory through the agency of the Federal Trade Commission and the Committee on Synthetic Drugs, it was necessary for the laboratory to work out adequate standards.¹⁴ As a result of the chemical work, a rather comprehensive monograph was drawn up, which was published in the 1918 Laboratory Reports. A summary of the products examined, with some of the chemical data, is given in Table 3. It will be seen that one specimen had a deficiency of about 2 per cent. of free base.

The melting point of the free base is given by a number of writers at 121 C. Although Kennert¹⁵ stated it to be 117 C. and not 121 C., his findings seemingly went unheeded. It will be noted that our work shows the melting point to be in accord with that announced by Kennert.

The Federal Trade Commission has not issued any licenses for the manufacture of "holocain hydrochlorid." The John T. Milliken Company has withdrawn its application. The H. A. Metz Laboratories (Suc-

TABLE 3.—DATA ON PHENETIDYL-ACETPHENETIDIN HYDROCHLORID

Manufacturer	Appearance	Moisture	Melting Point	Phosphorus Compounds	Phenetidin* Reaction	Indol Reaction	Ash	Per Cent. Base by Weight	Per Cent. Base by Titration	Melting Point of Base	Per Cent. Platinum in Platinum Salt +2
John T. Milliken Co.,	White crystalline powder	5.13	191.5 to 192	Absent	Negative	Positive	0.00	89.16	89.16	116 to 117	19.02
Synthetic Products Co., ..	White crystalline powder	2.90	192 to 192.5	Absent	Negative	Positive	0.13	87.49	87.26	116 to 117	19.3
H. A. Metz Laboratories, Inc.	White crystalline powder	4.99	192 to 192.5	Absent	Negative	Positive	0.00	89.14	88.55	117	19.24

* The phenetidin test is not very sensitive.

and Hilpert found 11.02 per cent. of sodium in "medinal," and 11.01 per cent. of sodium in "veronal-sodium." The theoretical amount, according to the formula given for medinal by the proprietors ($\text{C}_{11}\text{H}_{13}\text{COONaO}_2$) is 11.19 per cent. When an aqueous solution of barbitol sodium was acidified, and the diethylbarbituric acid extracted with ether, it was found that the amount of freed acid extracted varied directly with the length of time after acidification.

It is possible that in preparing the sodium salt of diethylbarbituric acid, the ring opens up, forming a compound not so easily affected by dilute mineral acids.

PHENETIDYL-ACETPHENETIDIN HYDROCHLORID¹⁴ (HOLOCAIN HYDROCHLORID)

Phenetidylacetphenetidin hydrochlorid was introduced in the United States under the name "holocain hydrochloride" by Farbwerke, vorm Meister Lucius and Bruening, Hoechst a. M. Germany; the product apparently had not been patented in this country, although it was protected in Germany under patents No. 78,868 and 80,568. New and Nonofficial Remedies, 1918, describes "holocain hydrochlorid" as

cessor to Farbwerke Hoechst Company, New York) are making the product in this country.

CINCHOPEN (PHENYLENCINCHONIC ACID, U. S. P.; ATOPHAN)

Cinchopen (phenyleinchoninic acid) was introduced in the United States as a medicine under the proprietary name "atophan," by Shering and Glatz, New York City, who before the war were the American agents for the German manufacturers "Chemische Fabric auf Actien von E. Schering, Berlin." Phenyleinchoninic acid (2 phenyl-quinolin-4 carboxylic acid) was first described by Doebner and Gieseke¹⁶ in 1887, who prepared it by warming together pyro-racemic acid, benzaldehyde and aniline in alcoholic solution; it has the structural formula:

The chief use of phenyleinchoninic acid is as an antitumor agent, especially indicated in gout.

¹¹ Puckner, W. A., and Hilpert, W. S., Veronal Sodium and Medinal, J. A. M. A. 5:2:111 (Jan. 23) 1909; Rep. A. M. A. Chemical Lab., 2:13.

¹² Since this was written, the Council on Pharmacy and Chemistry has also accepted "Barbital Sodium Abhor."

¹³ No short, scientific name has been given for this substance although several are under consideration.

¹⁴ Certain chemical tests are described by E. H. Rankin, Indian J. M. Res. 1:237, 1916; also Chem. Abst. 10:524. Other references are: Schmidt, Pharmazeutische Chemie 2:990. Reibstein H. (403). Arends, G. Z. Neue Arzneimittel und pharmazeutische Spezialitäten, Ed. 4, 1913, p. 271.

¹⁵ Kennert, Chem. Zentralbl. 2:556, 1897.

¹⁶ Doebner and Gieseke, Ann. d. Chem. (Liebig) 240:291, 1887.

In 1913, the German house of Schering was made the assignee of patent 1,045,759 granted by the United States government¹⁷ for the manufacture of phenylcinchoninic acid; at about the same time the product was admitted to the U. S. Pharmacopeia IX, under very loosely constructed standards.

Some time after the beginning of the European war the proprietary "atophan" became scarce in America. In 1917, however, Schering and Glatz, New York, placed American-made atophan on the market and submitted it to the Council on Pharmacy and Chemistry. Later, other firms began to manufacture the product and also submitted specimens. During the time it was investigating these products, the Federal Trade Commission decided that a license was needed to manufacture phenylcinchoninic acid under the patent just referred to, so that altogether the laboratory had a number of specimens to examine.

In making the examinations for the Council, the laboratory was practically confined, by virtue of the Food and Drugs Law, to limit its requirements of purity to those of the Pharmacopeia. Practically, the only tests were melting point, ash and solubility. According to the U. S. Pharmacopeia the melting point is "about 210." In New and Nonofficial Remedies, 1918, it was explained that atophan "complies with the standards for phenylcinchoninic acid, U. S. P., but melts between 208 and 212 C." The U. S. Pharmacopeia requires that no weighable ash remains on incinerating about 0.5 gm. of phenylcinchoninic acid. Considerable variations, especially in melting points, were found, as can be seen from Table 4.

By referring to this table on melting points and ash content it will be noted that the production of a better grade of products resulted after the respective firms had submitted samples to the A. M. A. Chemical Laboratory for criticism, and from a chemical standpoint, the last products examined were found to be as satisfactory as the German-made "atophan."

Solubility of Cinchophen (Phenylcinchoninic Acid.)
—As methods of determining impurities, or estimat-

ing the degree of purity of phenylcinchoninic acid were not described in the U. S. Pharmacopeia, it was decided to try extraction methods.¹⁸ This in turn led to the question of solubilities. The U. S. Pharmacopeia gives the solubility of phenylcinchoninic acid only in general terms; hence it was deemed advisable to determine its solubilities and describe them in more definite terms. The sample of phenylcinchoninic acid employed to determine the solubility

was obtained by repeated recrystallization from alcohol of a commercial specimen. Solubilities were determined in water, 95.0 per cent.; alcohol, 48.5 per cent.; alcohol,¹⁹ chloroform and ethyl acetate.²⁰ Complete saturation of the solvent was attained according to the U. S. P. IX method (p. 599). The bath was maintained at a temperature of 25 C., with a range of ± 0.2 degrees. The solution was analyzed by the method of Seidl.²¹ The data obtained for the solubility of phenylcinchoninic acid are given in Table 5.

The Abbott Laboratories, Chicago, have been licensed by the Federal Trade Commission to man-

TABLE 5.—SOLUBILITY OF CINCHOPHEN

Solvent	Gm. per Hundred- gram of Sat. Solution	Solubility, Parts per Weight
Distilled water	0.009	1 in 6,360
95 per cent. ethyl alcohol	0.833	1 in 119.0
95 per cent. ethyl alcohol	0.877	1 in 114.6
Chloroform	0.1075	1 in 9.97
Ethyl acetate	1.154	1 in 20.6

ufacture cinchophen. Other firms, however, have decided to manufacture it without the formality of obtaining a license, evidently considering the German-obtained patent not to be valid.²²

PROCAIN (NOVOCAIN)

Procain was introduced in medicine under the proprietary name "novocain," and before the war was obtainable in this country only through the Farbwerke Hoechst Company, the American representative of the German establishment, Farbwerke vorm Meister Lucius Brueening, Hoechst a. M. Chemically it is the mono-hydrochlorid of para-amino-benzoyl-diethyl-amino-ethanol, having the structural formula:

It is prepared, according to U. S. patent No. 812,554 (issued to Alfred Einhorn, Munich, Germany) by treating para-nitro-benzoylchlorid with ethylene chlorhydrin and diethylamin with subsequent reduction of the nitro groups, the resulting product being purified by recrystallization.

Procain is employed largely in infiltration anesthesia. It is less toxic than cocaine, but its anesthetic action is not sustained. This drawback is overcome by the simultaneous injection of epinephrin, and for this reason procain is often compounded with epinephrin in tablets, thus obviating the necessity of separate solutions.

When the first specimens of the American-made product were submitted through the channels of the Federal Trade Commission, it was necessary to compile a monograph.²³ This was prepared from descriptions in the available literature, mostly from tests described in New and Nonofficial Remedies, 1918, and the German Pharmacopeia V.

The submitted products were found satisfactory chemically. The toxicity determinations made by Dr. R. A. Hatcher, with the assistance of Dr. Carey

19. This corresponds to "distilled alcohol, U. S. P."

20. The ethyl acetate was Merck's product (distilled), stated to contain 84.6 per cent. of ethyl acetate, 10 per cent. alcohol and alcohol derivatives.

21. Seidl, A.; Bull. 67, Hyg. Lab. U. S. P. H. S., p. 11.

22. Very recently the Chemical Foundation, Inc., has undertaken to grant licenses for cinchophen. The Calco Chemical Company has obtained one.

23. The monograph appears in New and Nonofficial Remedies, 1919.

TABLE 4.—MELTING POINTS AND ASH

ing the degree of purity of phenylcinchoninic acid were not described in the U. S. Pharmacopeia, it was decided to try extraction methods.¹⁸ This in turn led to the question of solubilities. The U. S. Pharmacopeia gives the solubility of phenylcinchoninic acid only in general terms; hence it was deemed advisable to determine its solubilities and describe them in more definite terms. The sample of phenylcinchoninic acid employed to determine the solubility

17. The validity of this patent is to be doubted.

18. Attempts were made to make salts of phenylcinchoninic acid with metals such as copper, mercury, barium and calcium, and also the chloroplatinic acid or periodid addition products. Reliable quantitative results could not be obtained.

Eggleston²⁴ indicated that none of the specimens are to be considered dangerous when used in ordinary dosage for normal individuals. Therefore the Federal Trade Commission, on recommendation of the Committee on Synthetic Drugs of the National Research Council (aided by the A. M. A. Chemical Laboratory), issued licenses for the manufacture of procain to the Farbwerke-Hoechst Company (which license was later transferred to the H. A. Metz Laboratories), to the Abbott Laboratories, to the Calco Chemical Company and to the Rector Chemical Company.

Subsequently the products of the licensed firms were submitted to the Council on Pharmacy and Chemistry, which in turn invoked the aid of the A. M. A. Chemical Laboratory and the Cornell University Pharmacologic Laboratory. Later the Council asked the laboratory to examine the market supply. Altogether, therefore, a number of products were examined which were found to respond satisfactorily to the tests outlined in Table 6).

* U. S. Patent 815,471, the procain patent, declares that the salt must be dried to a constant weight, both the German Pharmacopoeia and past editions of New and Nonofficial Remedies give this melting point. Two specimens of German-made procain obtained from our files, stated to be manufactured by Farbwerke-Hoechst vorm. Meister, Pintsch and Baumgarten, Hoechst a. M., were found to melt, respectively, between 151 and 151.5 C. and between 153.5 and 154.5 C. when the melting point was determined according to the direction of the U. S. Pharmacopoeia, fourth revision. The various specimens examined at that time melted between 153 and 155 C. and it was decided to permit this range.

An examination of some American-made procain-supaparenin tablets was also made. The procain was determined by liberation of the alkaloid with ammonia water, extraction with chloroform evaporation of the chloroform, dissolving the alkaloid in one hundredth normal sulphuric acid solution and titrating excess acid with one hundredth normal sodium hydroxyl

solution. The epinephrin was determined according to the method employed by Seidell,²⁵ with slight modifications. The tablets contained the claimed amounts of ingredients.

THE SYNTHETIC DRUG SITUATION

Before the war, the American physician was literally bombarded with new and wonderful (?) coal-tar synthetics, most of which were originated in Germany. In fact, it seemed that if a by-product in the manufacture of dyes could not be used for a dye per se, then a place might be found for it in the ever increasing lists of medicaments. By clever advertising and propaganda among physicians, an artificial stimulation for coal-tar drugs was created which evidently yielded lucrative financial returns. As a result of the war, it is interesting to observe that of all the synthetic drugs imported into this country from Germany and on which the American patents were controlled by the Germans (up to the time of our entrance into the war), the demand was really sufficient enough to warrant the commercial manufacture of only four of them by American firms. Of course, a larger number of *unpatented drugs*, also imported from Germany, are now being made in sufficient quantities in this country; many of the drugs in this class were never patented or are the ones which have survived after the patent had expired, such as acetanilid, acetphenetid, and acetylsalicylic acid.

In view of the agitation to found an institute for cooperative research as an aid to the American drug industry under the auspices of the American Chemical Society, it will be well for the medical profession to be on its guard against too enthusiastic propaganda on the part of those engaged in the laudable enterprise of promoting American chemical industry. Unless it is, it may be inflicted in the future, as in the past, with a large number of drugs that are either useless, harmful or unessential modifications of well-known pharmaceuticals. It will be well also for the chemists—those engaged in this enterprise—to be sure that the product is of therapeutic value before asking its use as a medicine. The American medical profession has learned that relatively few of the many German synthetics were really valuable or decided improvements over established drugs. If American chemists desire to retain their prestige with the medical profession, they should earnestly endeavor to see that the advantages derived from the war and from such an institute as proposed are not abused in the worthy desire to popularize chemistry both educationally and commercially. They should realize that physicians are in no receptive mood for a flood of synthetics, even though "American-made."

On the other hand, the constructive possibilities of chemistry in the service of medicine should serve as a stimulus for American research. Notwithstanding all the pharmaceutical shirkery which Germany sent to us, still it did contain some synthetics that were worth while. As therapeutics has been benefited by these organic chemicals, it is logical to reason by analogy that there remain other synthetics to be discovered which will occupy places of equal distinction in the modern materia medica. For example, vaccines are of undoubted merit in the field of immunology, but their action is, in the end, chemical; as soon as chemical technique is refined by medicochemical research,

* The report of these and subsequent toxicity experiments on procain appeared in the report of the Council on Pharmacy and Chemistry, J. A. M. A. 72:1436 (Jan. 11) 1919.

²⁵ Seidell, J. Biol. Chem. 11:19, 1913.

it is quite possible that a definite chemical agent (synthetic) will supersede the indefinite bacterial vaccines. Obviously the American chemist has the opportunity of showing his resourcefulness in aiding the public health of America and the world. In this connection, a cooperative institute devoted to purely scientific drug research, and governed in such a manner as to inspire confidence in its humanitarianism and unbiased judgment, should serve a most commendable purpose. The hopes of American men of science are for a monumental research institution—cooperative with all the allied professions—and, as the *Chicago Chemical Bulletin* stated, "Stripped of all professional or commercial pettishness and not dominated by any one group of scientists."²⁰

CONCLUSIONS

As for the results of the work so far, they can be summed up in two sentences.

1. American chemists are producing synthetic drugs formerly controlled by Germany, and thus have declared their independence of German chemicals.

2. Judging from the evidence at hand, we can feel assured that the quality of American synthetics will be second to none.

ALLERGY IN DRUG IDIOSYNCRASY*

ROBERT A. COOKE, M.D.

NEW YORK

It is my purpose in this paper to call attention to some of the peculiar drug reactions occurring in man and, at the same time, to offer an explanation of them.

In a perusal of the recent textbooks on pharmacology, it was found that the word "idiosyncrasy" appears in all; but the definitions are almost as numerous as the books themselves, and in none is there any explanation for the peculiar effects of many drugs on certain people.

Given a normal person, any drug exhibited in therapeutic doses manifests a certain normal action, a side action and, in larger amounts, a toxic action, both the normal and the toxic action being more or less definitely fixed, symptomatically, for all individuals of the same species.

On the other hand, there are individuals within any species that manifest exaggerated normal and side actions from many such reasons as alterations in rate of absorption, excretion or destruction within the organism, or instability of the mechanism through which some drugs act. For example, the stimulating action of morphin, occasionally seen, is due to an exaggeration of the normal stimulating effect, which is usually marked by depression. The lessened normal action (or tolerance) is usually dependent on long-continued use of the drug. This may not be the case. The explanation of tolerance undoubtedly varies with different drugs, and a discussion of it will not be attempted here. These exaggerated normal and side actions and lessened action (or tolerance) should be included under the general heading "idiosyncrasy," and separated entirely from the abnormal actions now to be considered, and for which explanation is offered.

ALLERGIC ACTION OF DRUGS

In a former paper, with Vander Veer, I was able to estimate that approximately 10 per cent. of all human beings manifest some form of hypersensitiveness. By this is meant that such persons react in a peculiar and specific way to substances that are innocuous in anything like such doses to the average individual of the race.

Coca's classification of hypersensitiveness into "anaphylaxis" and "allergy" will serve to clarify this whole field, which has been confused by the attempt to explain natural and artificial hypersensitiveness on the same basis.

Anaphylaxis is an antigen antibody reaction, artificially induced by immunologic processes. Allergy is used to express the natural hypersensitiveness of the individual not produced by immunologic processes, as the exciting agents or allergens are in many cases not capable of producing antibodies. For example, the natural hypersensitiveness of the human being to pollens, the clinical reaction to which is known as hay-fever, is admittedly allergic. In experiments carried on with Coca and Flood, we could not demonstrate antibody in the individual during an attack or after injection of pollen extract by passive transfer, nor could antibody be produced in the guinea-pig itself. In other words, the extract is nonantigenic. Other substances, such as glue and certain drugs like acetylsalicylic acid, to which individuals react peculiarly, are also nonantigenic. To be sure, many of the substances to which the human being does show clinical hypersensitiveness are capable of forming antibodies. Hence the confusion between the natural hypersensitiveness or allergy and the artificial or anaphylaxis.

PROOFS OF ALLERGIC NATURE OF DRUG REACTIONS

Inheritance.—One of the proofs of the allergic nature of abnormal drug reactions is the fact that it is established by inheritance. Natural human hypersensitiveness has been shown by Vander Veer, in collaboration with me, to be an inherited trait, and one inherited, according to the mendelian law, as a dominant characteristic. Of the fifteen cases of drug reactions which form the basis of this paper, a positive antecedent history of hypersensitiveness existed in twelve, and in the other three there were evidences of other forms of allergy, such as asthma, urticaria and hay-fever, in the individual himself.

Symptomatology.—The symptoms of drug reaction or allergy are absolutely separate and apart from any normal or toxic action, and are the same as those occurring with foods, pollens and animal emanations. The symptoms are coryza, cough, bronchial spasm with urticaria in some cases, or angioneurotic edema, and frequently gastro-intestinal manifestations, with pain, vomiting and diarrhea. Occasionally, with the antipyretics, hyperpyrexia occurs or cardiac collapse and, in practically all, a marked eosinophilia, from 10 to 15 per cent. I shall speak particularly of the acetylsalicylic acid reactions, as these have been most frequently encountered thus far. Symptoms begin, as a rule, from fifteen to twenty minutes after the ingestion of 10 grains of the commercial drug. In nine of the fifteen cases, violent bronchial asthma was induced and one case was almost fatal from asphyxia. The attack lasts from eight to thirty-six hours, and in one instance was prolonged for three weeks. In only three of the cases was urticaria present. Con-

26. Proposed Institute for Drug Research, editorial *Chicago Chem. Bull.*, April, 1919, p. 67.

*Read before the Section on Pharmacology and Therapeutics at the Seventeenth Annual Session of the American Medical Association, Atlantic City, N. J., June, 1919.

stitutional reactions lasting three days have been produced after an intradermal test containing not more than 0.1 grain of acetylsalicylic acid. The onset of symptoms in these cases is almost immediate. Positive cutaneous reactions by testing are not obtained except in those cases in which there is a clinical history of urticaria. In other words, skin hypersensitiveness as a rule does not exist.

In some cases, the allergic reactions are delayed. In the literature are reported instances of allergic drug reactions appearing from five to twenty days after the primary injection.

Specificity.—The reactions seem to depend in most cases on the chemical molecule as a whole; in a few cases, on some fraction of the molecule. Three of the cases that showed a bronchial reaction to acetylsalicylic acid gave no reaction to salicylic acid, benzoic acid, antipyrin, sodium acetate or methyl salicylate. On the other hand, many of the instances of drug reactions reported in the literature are shown to be due to fractions of the molecule. For example, iodoform hypersensitiveness has been shown to be due to the CH_3 group, and not to iodine or ioid.

No attempt is made here to give a complete summary of the subject of drug allergy. I merely wish to emphasize the conception that such a condition exists, and that it should not be confused with what are ordinarily and properly classified as idiosyncrasies. In order to clarify the ideas on drug action, it seems possible to make tentatively some such classification as the following:

1. Normal action—side action and toxic action.

2. Idiosyncratic action—(a) exaggerated normal action; (b) exaggerated side action; (c) lessened normal action (tolerance).

3. Allergic action—abnormal action.

No attempt is made in this classification to include racial variations, which are not idiosyncratic except when comparing one species with another which has an entirely different organic or functional mechanism.

ABSTRACT OF DISCUSSION

DR. LAMBERT OTT, Baltimore: I was interested in hearing Dr. Cooke's report in regard to the sensations following the injections of acetylsalicylic acid. It must be interesting to know this condition. Some years ago I reported such a case which I called an idiosyncrasy; for after all, these conditions are produced by some chemical. I saw a patient, 37 years of age, who took acetylsalicylic acid and developed bronchial spasms. Sometimes he was advised what he was taking and sometimes not. The drug was administered in capsules and in powders, and in every instance the man developed bronchial spasms.

The Record of Vaccination. In the Municipal Hospital of Philadelphia, during thirty-four years, in which time over 9,000 cases of smallpox have been treated, no physician, nurse or attendant who has been successfully vaccinated or revaccinated prior to going on duty has contracted the disease. On the other hand, in the Fever Hospitals of London, according to Ernest Hart, in 1893, of 2,484 persons employed, 130 became infected and two died; seventy-three had scarlet fever and twenty-three contracted diphtheria. The deaths from smallpox, in England, are thirteen per million for medical men (who are well vaccinated) as against seventy-three per million of the general population; whereas fifty-nine medical men per million die of scarlet fever as against sixteen per million of the general population.—Welch and Schanberg, *Acute Contagious Diseases*.

FILARIAL PERIODICITY*

KENNETH M. LYNCH, M.D.

CHARLESTON, S. C.

A most interesting phenomenon in blood parasitology and one of practical importance in the question of transmission of the parasite, is the periodicity of filariae. This term has come to mean a periodic increase in numbers in peripheral capillary blood of the embryos of filariae. This, in the case of *Filaria bancrofti*, occurs during the hours of sleep, and of *Filaria loa*, during the hours of activity. Until Smith and Rivas¹ developed the acetic acid concentration method of counting the number of microfilariae in a given amount of blood, "filarial periodicity" signified the periodic appearance and disappearance of microfilariae in the peripheral blood. This acetic acid concentration method of examining for microfilariae has brought about important changes in our conception of the phenomenon, and has opened a new avenue of approach to the problem.

Smith and Rivas have thus been enabled to show that filaria embryos are to be found in the peripheral blood at all times of the day and night, and that the periodicity is a matter of a relative number of embryos circulating in the blood. They² have given a method of making an exact count, and they have been led to formulate a new theory as explaining the phenomenon.

They have shown that the period of cutaneous prevalence of *Microfilaria bancrofti* is from midnight to 8 a. m., the maximum being about 2 a. m.; that the period of cutaneous prevalence of *Microfilaria loa* is from 8 a. m. to 4 p. m., the maximum being about noon, and that from 4 p. m. to midnight is a period of cutaneous paucity of both.

Regarding these periods as those respectively of (a) greatest peripheral relaxation from fatigue and sound sleep; (b) of recovery from fatigue and the resumption of capillary tone in the periphery, and (c) of capillary constriction from the combined influences of tone and of compression from muscular activity, and believing that both microfilariae are restricted (but not prevented) in their motility by their ensheathment, *Microfilaria loa* exerting greater motile effort than *Microfilaria bancrofti*, Smith and Rivas advance a theory in which the mechanics of the capillary circulation plays the main rôle, with the restricted motility of the parasite playing a minor part. In brief, the theory considers that the parasites are both in smallest numbers when they have the easiest progress through relaxed capillaries (the period of relaxation, 4 p. m. to midnight), that *Microfilaria bancrofti* is caught by the first resumption of capillary tone (from midnight to 8 a. m.), that the parasites get through, finally, by the end of this time, and are then held up again in the pulmonary capillaries, and that *Microfilaria loa*, because of greater motile effectiveness is enabled to pass this moderate opposition; but when the capillaries are markedly diminished from tonic contraction and muscular compression (8 a. m. to 4 p. m.), the parasites are no longer able to progress easily, and therefore accumulate.

2. Smith, A. J., and Rivas, Damaso: Notes Upon Human Filariasis, Am. J. Trop. Dis. & Prev. M., 2: 301, 1914-1915.

Supporting the mechanical part played in this theory, Smith and Rivas have performed some experiments aiming at altering circulatory conditions and capillary caliber. They succeeded, at one time, in increasing the number of *Microfilaria loa* by giving a half ounce of brandy; at another, by a half hour's general exercise, and by compressing the hand in a glove, and placing the hand in warm water. They also determined that the venous drainage of an extremity showed fewer parasites than did the capillary circulation.

Manson³ considers broadly that the periodic peripheral swarming of microfilariae is an adaptation on the part of the parasite to the biting habits of the intermediate host. Undoubtedly, the large numbers of *Microfilaria bancrofti* in the peripheral blood at night favor its entrance into the night biting *Culex fatigans*, but this does not explain the problem. Manson would believe that there is some physiologic product, the outcome of the activities of waking life, which either drives *Filaria nocturna* from the surface of the body during the day, or attracts it to certain internal organs, particularly to the lungs and large arteries.

Feeling that this chemotropic theory is rather unreasonable and that the demonstration of these embryos constantly in the peripheral blood has rendered it untenable, I have instituted a series of experiments in the human infection by *Filaria bancrofti*, and the dog infection by *Filaria immitis*, attempting to influence the number of embryos in capillary blood by circulatory alteration.

In all of these counts I have used the acetic acid method of concentration, taking 1 c.c. of blood in 10 c.c. of 2 per cent. acetic acid solution, centrifuging, washing and recentrifuging several times, spreading the sediment on a slide, and counting the whole number in the sediment.

NITROGLYCERIN EXPERIMENTS

EXPERIMENT 1.—*Human case of Filaria bancrofti*.—In J. S., an aged colored man with extreme arteriosclerosis, poor mentality, motor nervous disturbance, markedly enlarged right inguinal glands, hydrocele and general lymph gland enlargement, microfilariae were found in a drop of blood from the finger tip at 11 p. m.; none in the day time. Dec. 11, 1916, at 11 a. m. 245 microfilariae in 1 c.c. of blood from the finger tip were counted. I gave $\frac{1}{100}$ grain of nitroglycerin hypodermically. At 11:30 a. m. 171 microfilariae were found in 1 c.c. of blood from the finger tip, a decrease of seventy-four, or 30 per cent. Dec. 13, 1916, at 11 a. m., I repeated the experiment and counted 201 per cubic centimeter before the administration of the nitroglycerin, and seventy-four per cubic centimeter twenty minutes after the administration, a decrease of 127, or 63 per cent. Dec. 19, 1916, at 11 p. m., I repeated the experiment, and counted 615 microfilariae per cubic centimeter before, and 615 per cubic centimeter twenty minutes after the administration of nitroglycerin.

EXPERIMENT 2.—*Human case of Filaria bancrofti*.—In T. R., a middle aged mulatto, showing chyluria, there were counted, Dec. 13, 1916, at 11 a. m., three microfilariae per cubic centimeter in the blood of the finger. I gave $\frac{1}{100}$ grain of nitroglycerin hypodermically and, at 11:20 a. m., counted one microfilaria per cubic centimeter of blood from the finger. Dec. 19, 1916, at 11 p. m., I repeated the experiment and counted 382 microfilariae per cubic centimeter before, and 300 per cubic centimeter twenty minutes after the administration of the nitroglycerin, a decrease of eighty-two, or 21 per cent. Jan. 5, 1917, at 11 p. m., I repeated the experiment and counted 353 microfilariae per cubic centimeter before, and 259 per cubic centimeter after the administration, a decrease of ninety-four, or 26 per cent.

EXPERIMENT 3.—*Dog, infected with Filaria immitis*.—Dec. 17, 1917, at 11 a. m., there were counted 2706 microfilariae per cubic centimeter in the blood from the ear. One one-hundredth grain of nitroglycerin was given hypodermically. At 11:15 a. m. there were 972 microfilariae per cubic centimeter in the blood from the ear, a decrease of 1,734, or 64 per cent. Dec. 19, 1917, at 11 a. m. the experiment was repeated, and 3,264 microfilariae were found per cubic centimeter before, and 3,264 per cubic centimeter five minutes after administration of nitroglycerin.

Jan. 5, 1917, at 11 a. m., the experiment was repeated. There were counted 3,172 before, and 1,620 after administration of the nitroglycerin, a decrease of 1,552, or 50 per cent.

Thus, after the administration of nitroglycerin, there resulted decreases in the number of both *Microfilaria bancrofti* and *Microfilaria immitis* in the peripheral capillary blood, varying from 21 per cent. to 64 per cent. In two experiments, one with *Microfilaria bancrofti* and one with *Microfilaria immitis*, the number remained the same in twenty and five minutes, respectively. I have recorded in my notes that the product used in these was old and its potency doubtful. It was not tested, but a fresh product was substituted. I interpret these results to indicate that relaxation of the vascular system, whether during the period of cutaneous prevalence or paucity, allows these parasites to pass more freely, and consequently their number in a given volume of blood decreases.

PITUITARY EXTRACT AND EPINEPHRIN EXPERIMENTS

EXPERIMENT 4.—*Human case*.—In J. S., Dec. 17, 1916, at 11 p. m., there were counted 531 microfilariae per cubic centimeter in blood from the finger. He was given pituitary extract hypodermically, and there were counted 665 microfilariae per cubic centimeter in the finger's blood at 11:10 p. m., an increase of 134, or 25 per cent.

EXPERIMENT 5.—*Human case*.—In T. R., Dec. 15, 1916, at 11 p. m., there were counted 227 microfilariae per cubic centimeter in the finger's blood before, and 334 ten minutes after the administration of pituitary extract, an increase of 107, or 47 per cent. Dec. 17, 1916, the experiment was repeated, and there were counted 138 per cubic centimeter before, and 364 per cubic centimeter twenty minutes after the administration of pituitary extract, an increase of 226, or 164 per cent.

EXPERIMENT 6.—*Dog, Filaria immitis*.—Oct. 29, 1917, at 11:55 a. m., 1,360 microfilariae were found per cubic centimeter in blood from the ear before, and 1,620 microfilariae per cubic centimeter in blood from the ear ten minutes after the administration of 1 c.c. of pituitary extract hypodermically, an increase of 260, or 20 per cent. At the same time, 1,050 per cubic centimeter were found in blood taken directly from a large ear vein. This confirms the observation of Smith and Rivas in *Filaria bancrofti* infection. The experiment was repeated, Oct. 31, 1917, at 12:30 p. m., and 1,294 microfilariae per cubic centimeter were found before, and 2,678 per cubic centimeter of ear's blood ten minutes after the administration of pituitary extract, an increase of 1,384, or 107 per cent.

Nov. 1, 1917, at 12:30 p. m., the experiment was repeated and there were counted 1,478 microfilariae per cubic centimeter in capillary blood from the ear, 1,272 per cubic centimeter in venous blood, and, ten minutes after the administration of pituitary extract, 2,196 in capillary and 724 in venous blood, an increase in the capillary blood of 718, or 48 per cent., and, at the same time, a decrease in the venous blood of 448, or 35 per cent., thus showing that the increase in the capillary blood was a process of accumulation or holding up, and not an additional influx.

The experiment was repeated, Nov. 2, 1917, at 11:20 a. m. One thousand nine hundred and twenty-two microfilariae per cubic centimeter were counted in the capillary blood before, and 2,160 per cubic centimeter ten minutes after the administration of epinephrin, an increase of 238, or 13 per cent. Twenty minutes after the administration, 2,460 microfilariae per cubic centimeter were found in venous blood. It seems that prob-

ably by this time the parasites were being released into the veins. Unfortunately, capillary blood was not taken.

The experiment was repeated, Nov. 5, 1917, at 11:30 a. m., and 2,216 microfilariae per cubic centimeter of capillary blood were counted before, and 2,820 per cubic centimeter ten minutes after the administration of epinephrin, an increase of 603, or 27 per cent., and 3,228 per cubic centimeter twenty minutes after the administration, an increase of 1,012, or 45 per cent.

The experiment was repeated, Nov. 9, 1917, at 11 a. m. Two thousand three hundred and seventy-two per cubic centimeter of capillary blood were found before, and 3,512 thirty minutes after administration of epinephrin, an increase of 1,140, or 48 per cent., and 4,420 per cubic centimeter in capillary blood forty minutes after the administration, an increase of 2,048, or 86 per cent.

A dog was anesthetized with morphin and chlorbutanol, Jan. 12, 1918, at 11 a. m. There were counted 3,268 microfilariae per cubic centimeter in capillary blood before, and 4,738 per cubic centimeter in capillary blood ten minutes after the administration of epinephrin, an increase of 1,470, or 45 per cent.

Therefore, after the administration of epinephrin and pituitary extract, there resulted increases in the number of both *Microfilaria bancrofti* and *Microfilaria immitis* in the peripheral capillary blood, varying from 13 to 164 per cent. There occurred also a decrease of 35 per cent. in the venous drainage of an area at the same time as an increase in the capillary blood of 48 per cent. and a subsequent venous increase. I interpret these observations to indicate that an increase in the tone of the vascular system, whether during the period of peripheral prevalence or paucity, prevents the free passage of these parasites through the capillaries; that, therefore, their number in a given volume of capillary blood increases, and that during this time the number getting into the venous drainage is cut down, but increases after a time, and especially when the tone begins to wear off.

EFFECT OF SLEEP

The effect of sleep on the peripheral prevalence of *Microfilaria immitis* was shown in the following experiment:

EXPERIMENT 7.—Dog 1, was kept awake from 11:20 a. m. to 1 a. m. following, and the capillary blood showed, at 11:20 a. m., 2,851 microfilariae per cubic centimeter; at 1 p. m., 2,900; at 3:20 p. m., 3,217; at 8 p. m., 2,736; at 11 p. m., 2,352, and at 1 a. m., 2,264.

In Dog 1, awake at 1 p. m., there was a count of 2,512 in the capillary blood, and, in Dog 1, asleep at 3 p. m., a count of 4,300 in the capillary blood, an increase of 71 per cent., which is comparable to but not as large, even, as the increase brought about by pituitary extract and epinephrin administration.

It is interesting to note that when the dog was kept awake there was an increase comparable to that of *Microfilaria loa* in the afternoon, and then a decrease similar to that in *Microfilaria loa* infection in the night hours. *Microfilaria immitis* is smaller in transverse diameter than *Microfilaria bancrofti* and *Microfilaria loa* embryos. As a consequence, it gets past the capillary barrier with more ease and shows constantly more in peripheral blood. There is, however, a period of relative peripheral prevalence directly connected with sleep, whether at night or in the day, which can be altered by keeping the dog awake, and the number of microfilariae in the peripheral capillary and venous blood is subject to the same natural and artificial alterations as is that of the human parasites.

In this connection, it would be interesting to know whether the acetic acid concentration method would not show a periodicity of the smaller human filaria embryos, *Filaria perstans* and *Filaria demarquayi*, which are to be found by old methods of examination constantly in the peripheral blood.

EFFECT OF COLLAPSE OF THE LUNG

EXPERIMENT 8.—Dog 1, anesthetized with chlorbutanol and morphin gave a count of 3,268 microfilariae in the peripheral capillary blood.

One lung was artificially collapsed by the introduction of air into the pleural sac. Five minutes later the dog died, and the thorax was opened. The uncollapsed lung showed 8,962 microfilariae in the capillary blood; the collapsed lung, 350,000 per cubic centimeter, this being a rough count as there were so many it could not be made exact; the left ventricle, 7,365, and the right ventricle, 10,778. Unfortunately, the bloods taken from various other parts were allowed to clot, and were consequently useless for counting.

This is one of the most striking of the experiments. The capillary circulation in the lungs is more of a barrier to the passage of these parasites in both *Microfilaria bancrofti* and *Microfilaria immitis* infections than is the peripheral capillary system, as is evidenced by the larger numbers in the uncollapsed lung of this dog and in Manson's case of *Microfilaria bancrofti* infection, which came to necropsy, and also in a case in which I made a postmortem examination. As shown by my necropsy, this appears to be not simply a retirement from the periphery to the lungs during the period of peripheral paucity. Apparently the lung filter is more or less constantly difficult of their passage. The collapse of the lung seems to have created a pressure on the capillaries and to have rendered them relatively impassable, even by this small worm, and to have led to an enormous accumulation, showing an increase over the number in the other lung of 3,805 per cent. in five minutes.

It is to be noted also that the number getting through the lungs and showing in the left heart was even less per cubic centimeter than in the uncollapsed lung.

I would interpret this experiment as showing what an influence on the number of these worms a purely mechanical capillary barrier may have.

HUMAN NECROPSY

Manson has reported a necropsy of a subject of *Filaria bancrofti* infection who died suddenly at 8 a. m., in whom he found prodigious numbers in the lungs, very many in the pulmonary artery and vein, large numbers in the carotid artery, a large number in clots from the left ventricle and aorta, many in the heart muscle, and a few in other places. From this he concludes that *Filaria nocturna*, during its temporary absence from the cutaneous circulation, retires to the localities in which he found large numbers.

Sept. 16, 1916, I performed a necropsy on a subject of *Filaria bancrofti* infection who died of pellagra at about 2 a. m. I was not at the time using the acetic acid method of counting, but I recorded large numbers of microfilariae in the lungs, and a few in the blood of the kidney, spleen, liver, heart, retroperitoneal lymph glands and large vessels. This confirms Manson's observation in regard to the lungs, but not in regard to the heart and large vessels. Neither of these cases furnishes positive reliable evidence of the distribution except in a rough way. I expect interesting exact data to be obtained from a repetition of postmortem exam-

inations by the use of the acetic acid method of counting. I can see no means by which the microfilaria could maintain itself against the current in the large vessels, particularly such as the aorta and carotid artery.

INTRAVITAM OBSERVATIONS ON MICROFILARIA IMMITIS

EXPERIMENT 9.—Dog 1 was anesthetized, the abdomen opened, and the omentum drawn over the stage of a microscope. Considerable injury was done and it was difficult to keep the membrane warm and moist. Consequently, the capillary circulation was largely sluggish or stopped. Three microfilariae were seen wriggling with the stream, faster than the blood was moving, in a large capillary. One was seen to progress against the stream of a small capillary. Two went slowly forward through a capillary carrying a single line of cells. These were wriggling, and the blood cells passed by them in their convolutions. This explains why even large numbers do not prevent the passage of blood in the small capillaries. The one progressing against the stream and those going forward faster than the sluggish stream appeared to push themselves against the wall. Apparently, therefore, they have some propulsive power even in the capillaries. It was planned to observe the action of drugs on the vessels, and the effect on the passage of the parasite, but the technic will have to be perfected before this can be done. I expect this measure, however, to furnish interesting information concerning the passage of microfilariae through the capillaries.

This experiment appears to show that the parasite does not perform simply as a foreign body but that its own activity is to some extent concerned in its passage of the finer capillaries, as was conjectured by Smith and Rivas.

FURTHER DRUG ADMINISTRATION

Incidentally, it may be mentioned that in the human experiments ergot and caffeine were administered without altering numbers, that emetin was given hypodermically with no effect on the parasite, and that while oil of chenopodium given intravenously in considerable doses in the dog killed the embryo, doses compatible with the life of the animal had no apparent effect, and neither did alimentary administration.

SUMMARY

Fully realizing the limitations to be placed on interpretations of the effect on the capillary system of the drugs used, and that these experiments need confirmation and elaboration, I believe that these observations strongly support the mechanical theory of Smith and Rivas in regard to filarial periodicity, and that the reasonable explanation of filarial periodicity is furnished by some such mechanical proposition, in which the caliber of the capillaries plays the main rôle, with the motility of the microfilariae playing a lesser part, so that the peripheral prevalence of microfilariae is largely dependent on the difficulty of passage of the peripheral capillaries during periodic tonicities and is directly related to sleep and wakefulness, but is affected to an extent varying with the size and the motility of the parasite, the pulmonary capillary system relative to these two conditions playing the part of a more or less constant barrier, but one probably more effective during the hours of the tone of activity.

CONCLUSIONS

1. The acetic acid concentration method of Smith and Rivas furnishes an exact method of counting microfilariae, and only by exact counts can the number in a given part of the body be accurately determined.

2. The administration of nitroglycerin is followed by a decrease in the number of *Microfilaria bancrofti* and of *Microfilaria immitis* in the peripheral capillary blood, during both periods of peripheral prevalence and paucity.

3. The administration of epinephrin or pituitary extract is followed by an increase in the number of *Microfilaria bancrofti* and of *Microfilaria immitis* in the peripheral capillary blood, during the periods both of cutaneous prevalence and of cutaneous paucity.

4. The period of cutaneous prevalence of *Microfilaria immitis* is directly connected with sleep.

5. In the collapsed lung, *Microfilaria immitis* accumulates in enormous numbers.

6. During the period of cutaneous paucity of both *Microfilaria bancrofti* and *Microfilaria immitis*, there are large numbers in the lungs.

7. The venous drainage of a part contains fewer microfilariae than the capillaries, there are still fewer when accumulation in the capillaries is produced by vascular stimulation, and following this capillary accumulation the venous drainage contains larger numbers.

TYPHOID, PARATYPHOID AND DYSENTERY CARRIERS AMONG RETURNING OVERSEAS TROOPS

EDWIN HENRY SCHORER, M.D.
(KANSAS CITY, MO.)

Lieutenant-Colonel, M. C. U. S. Army; U. S. Army Laboratory,
Port of Embarkation
HOBOKEN, N. J.

Circular 69, issued in February, 1919, by the chief surgeon of the American Expeditionary Forces stated that during the autumn and early winter of 1918 the incidence of typhoid and paratyphoid fevers among the American troops overseas had shown a noteworthy increase. More than 874 cases of typhoid and paratyphoid were reported between October 1 and February 1. This number, while not large in itself, represented an unexpected degree of infection among vaccinated individuals. The questions that presented themselves were: What percentage of the convalescents would become chronic carriers, and to what extent would these returning troops prove a menace to the home population?

It was therefore planned to examine the stools of a sufficient number of returning troops to include members of practically all divisions and at the same time to reduce the percentage of error. This laboratory seemed to be particularly well adapted for this purpose, not only on account of its facilities, but especially because of the fact that an intensive survey for intestinal parasites was being conducted among all homecoming men by Major C. A. Kofoed, S. C. U. S. Army.

The routine for the collection and examination of specimens was as follows:

The specimen of stool was placed in a cardboard drug can with tin bottom and top and immediately brought from the ward to the laboratory. A small portion (about the size of a pea) was thoroughly emulsified in 10 c.c. of nutrient broth and the tube placed in the incubator for two hours, during which time the larger particles settled to the bottom. A loopful of the suspension was then streaked on Endo agar and the plates were incubated over night. All colorless colonies were then fished to Russell's double sugar agar,

the slants incubated over night, and all cultures showing the characteristic reactions of typhoid, paratyphoid or dysentery bacilli were subcultivated on plain agar. Tests were then made for motility, and the various carbohydrate reactions were observed. Macroscopic agglutination tests were carried out with potent immune serums in a 1:100 dilution. The cultures were carried on plain agar slants for at least ten generations for the purpose of increasing their agglutinability, if possible. Before the final diagnosis was made, all cultures were plated, and single colonies were fished to plain agar slants. The carbohydrate fermentations were again tested in freshly prepared and incubated Hiss serum waters, their motility or absence of it verified in broth and Hiss semisolid medium, and their agglutinability carefully determined with the different serums in varying dilutions.

Of all the strains isolated from the stools of 1,000 men, only two gave sufficiently definite reactions to warrant their identification as true pathogens. One culture proved to be *Bacillus dysenteriae* of the Hiss-Russell-Y type while the other was *Bacillus dysenteriae* of the Flexner type. Neither of the men from whom these organisms were isolated had been or was suffering from bacillary dysentery. In addition to the above mentioned two, twenty-eight strains of nonlactose fermenters were isolated which gave carbohydrate fermentations characteristic of the types sought, but which agglutinated with their respective serums in dilutions of 1:100 and at most at 1:500. Since the serums used were of high titer (*B. typhosus* serum 1:32,000, *B. paratyphosus* A and B serums 1:16,000, and *B. dysenteriae* serum 1:4,000), and because repeated subcultivating on agar failed to increase the agglutinability of these strains, these organisms were finally classed as intermediates. Eleven other strains, which on preliminary tests fermented only glucose and mannite with gas and agglutinated with the paratyphoid serums in dilutions of 1:100 and 1:500, later fermented lactose after prolonged incubation. These were undoubtedly "slow colons." Their detection emphasizes the necessity of long incubation (two weeks) of the lactose serum water and litmus milk cultures, and also of carrying out agglutination tests in higher dilutions, before making any final bacteriologic diagnosis.

COMMENT

In only two individuals out of 1,000 returning overseas troops were any of the usual pathogenic intestinal gram-negative bacilli found. These men were found to be carrying dysentery bacilli of the Hiss-Russell-Y and Flexner types, respectively. No typhoid or paratyphoid bacilli were isolated. Therefore, only 0.2 per cent. of all men examined were found to be carriers. By way of comparison, it is interesting to mention the number of clinical cases of similar infections among returning troops. Of the 50,747 men passing through the hospitals of the Port of Embarkation during March, April and May, 1919 (the period covered by this bacteriologic study), six had typhoid fever, and one had dysentery of the Hiss-Russell-Y type, with no cases of paratyphoid fever. These give a percentage of 0.014 per cent.

No doubt, had time permitted the cultivating of all stools on brilliant green agar as well as on the Endo plates used, the isolations might have been greater in number. The method employed, however, was deemed to be sufficient to detect the great majority of infected individuals. The results as they stand, taken in conjunction with the record of clinical cases, would seem

to show that such infections as had occurred in the American Expeditionary Forces during the autumn and early winter of 1918 had remained limited and had given rise to no aftermath of carriers.

DIAGNOSTIC INCISION OF TUMORS

FRANCIS CARTER WOOD, M.D.

NEW YORK

It is now generally recognized that to obtain satisfactory results in the treatment of cancer, an early diagnosis is necessary; if an operation for cancer is to be successful, the diagnosis must be made almost always before the classic symptoms appear, often a matter of great difficulty. It is imperative, also, that no time be lost in making a decision and in planning the operation, for the scope of the latter, when the tumor is benign, is entirely different from that when the growth is malignant, and it is often most difficult to change during the course of the operation from one type of procedure to another. For instance, the extensive exposure and preliminary vascular ligation which may be necessary in a resection for cancer of the tongue, jaw, uterus or rectum are quite unnecessary in the case of a benign tumor, and to change the whole scheme after the operation has been begun may require more time than the patient's strength permits. An abdominal hysterectomy for fibromyoma may reveal carcinoma or sarcoma of the uterus, and the additional dissection required, if the proper operation is to be performed, may impose great risk from shock or hemorrhage on the patient, while a two-stage procedure is out of the question if a cure is to be obtained. The examples cited show that it is of the utmost importance that a correct diagnosis be had before operation; but often this is impossible without microscopic examination of the tumor.

EXCISION FOR MICROSCOPIC EXAMINATION

The procedure of excising a small fragment of a tumor for examination has long been employed by the dermatologists as a means for obtaining a definite diagnosis; but among the surgeons, opinions are not generally in accord, and of late years the practice of diagnostic excision has been subjected to much criticism, some of it entirely from a theoretical point of view, and some based on a moderate number of cases in which such incision was supposed to have incited the tumor to more rapid growth, or to have led to more widespread metastasis. The discussion culminated two years ago in a very bitter series of editorials in the *Medical Record*,¹ criticizing the action of the Department of Health of New York City and of the Cancer Commission of Harvard University in offering facilities for the diagnosis of excised fragments of tumors. The anonymous writer of these editorials went so far as to state that the incision of a tumor twenty-four or forty-eight hours before its removal was "little short of a crime," and that a physician making such an incision would have "no defense whatever if the heirs of his patient should bring a malpractice suit."

The whole question has been well discussed by Ewing,² who thinks biopsy justified if a diagnosis can-

¹ M. Rec. 91:156 (Jan. 27); 286 (Feb. 17); 371 (March 3); 731 (April 28) 1917, and 92:728 (Oct. 27); 1083 (Dec. 22) 1917.

² Ewing, James: The Incision of Tumors for Diagnosis, New York M. J. 102:10 (July 3) 1918.

not be made otherwise; while Greenough³ has published the results of a questionnaire, the general opinion which he obtained from surgeons being in condemnation of incision of the tumor under any circumstances. Bainbridge⁴ has reviewed this aspect of the literature of the subject and has brought forward some cases which he believes illustrate the dangers of diagnostic incision.

It cannot be denied that in the vast majority of instances of cancer presenting for operative treatment, the growth has reached such a point, unfortunately for the patient, that a surgeon well trained in pathology can make a diagnosis without the help of the microscope; but the knowledge possessed by a surgeon so trained is not universal, and I have seen many mutilating operations performed on patients with a variety of lesions which had been diagnosed clinically as cancer, but which were not malignant. These include three cases of complete excision of the tongue and a number of amputations of extremities. Again, there is still a tendency to treat ulcerated lesions of the mouth with medicine over too long a period, especially if the patient gives a positive Wassermann reaction. Unquestionably, arsenphenamin, by destroying the spirochetal organisms so frequent in the buccal cavity, does produce a certain amount of disinfection of the surface and, in consequence, some deceptive improvement, during which time deep extension of the tumor may take place.

On the other hand, the statement that exploratory incision into a tumor is invariably followed by local spreading or metastasis to regional lymph-nodes is not true. I have seen a number of cases of epithelioma of the tongue and the lip in which diagnostic fragments were removed without injurious result, the patient being alive and well from five to eight years after; and I have also seen one case of epithelioma of the tongue in which only partial extirpation was performed, and three weeks were allowed to elapse before a second operation took place; but, nevertheless, the patient is now, at the end of five years, alive and well.

The theoretical danger of opening up blood vessels has never seemed to me to have the extraordinary weight given it by clinicians, as the blood flow tends to wash particles out of the vessels cut, rather than into them, and the body is unquestionably able to take care of a certain number of free cancer cells, as Schmidt⁵ and others have shown. Furthermore, the effect of opening the lymph channels has not been studied scientifically. For example, it is usually assumed that the recurrences of the tumor along the scar, so frequent after amputation of the breast, are due to opening lymph channels; but experimental evidence makes it seem much more probable that both the handling of the tumor before operation, when it may be palpated by a dozen physicians for diagnostic purposes, and the manipulation of the organ during excision are much more likely to be the cause of the distribution of the tumor particles. The frequency with which hemorrhagic areas are found in tumors removed by operation and that with which freshly dislodged cancer particles can be demonstrated in the blood and lymph vessels suggests this explanation. The extraordinary dissemination produced by the massage treatment of tumors

of the breast, and the ease with which cancer cells can be distributed through the vascular system of a mouse whose cancer has been gently massaged for a minute or less, show that manipulation of a tumor is a very dangerous procedure.

EXPERIMENTS

The subject seemed an ideal one for attack from the experimental side. The occurrence of metastasis in human cancer depends on the size of the cells, the extent and situation of the tumor, the relationship between it and the lymphatic drainage system, and the amount of massage, both from the patient's handling of the growth and from muscular action compressing it; all these add to the problem in man variables whose values cannot be weighed. On the other hand, the use of one of the well known transplantable tumors, such as the Flexner-Jobling rat carcinoma, eliminates any question as to the size of the cells, the situation of the tumor, and the possibility of massage, the growth being implanted always in the same portion of the animal and at a site where it is not liable to be rubbed during the animal's movements. It is possible, also, to obtain accurate necropsy controls on animals whose tumors have been excised, a thing which is not possible in human cancer.

So far as I am aware, the question has not been approached experimentally except by Tytzer,⁶ who, in 1913, published a very important paper, chiefly concerned, however, with other phases of the metastasis problem. Apparently he did not excise small fragments of the tumors, but attempted a fairly extensive removal, such as would represent an incomplete operation, and he reached the conclusion that incomplete operations did not increase the incidence of metastasis. The number of animals used was small, and the work was done with a carcinoma in the Japanese waltzing mouse, the growth having a number of peculiarities, one of which was that the lymph-nodes were never involved.

For our experiments, a rat tumor which does metastasize generally was selected. The Flexner-Jobling rat carcinoma employed is an adenocarcinoma, which frequently metastasizes to the lungs, blood vessels and regional lymph-nodes. The inoculated tumors tend to remain discrete when a small graft is placed in the loose subcutaneous tissue of the side, and clean incision does not cause local spreading in the tissue planes. In suitable animals, the tumors take in a large percentage and grow progressively. The following experiments were carried out with the valuable assistance of my colleagues, Dr. Frederick D. Bullock and Dr. George L. Rhodenburg.

White rats, totaling 673, were inoculated with the Flexner-Jobling rat carcinoma, and divided into three groups. From those in Group I a portion of each tumor was excised aseptically, and the skin was then sutured over the wound. After ten to twelve days, this being the maximum time required to obtain a microscopic diagnosis, the entire tumor was carefully excised in order that the formation of metastasis might be checked. The animals were killed and examined from three to four weeks later. From the second group of animals, inoculated at the same time, the tumors were removed on the same day that the tumors were removed from Group I, and the animals were killed

and examined from three to four weeks later. This group thus formed a check on the first, for if the number of metastases was the same in both series, it would be evident that the incision of the tumors had not increased the amount of metastasis, since in both series the tumors had been in the animal body for exactly the same length of time and had been removed by exactly the same method. Great care was taken with the surgical technic, so as to avoid massaging the tumors, which, as Tyzzer⁸ has shown, and as more extensive experiments in my own laboratory have also demonstrated, is a most efficient means for distributing tumor particles throughout the body. The third group of inoculated animals was killed at the same time that the others were killed, and formed a check on the metastasizing power of the tumor.

RESULTS

The results may be thus summarized:

The average percentage of metastases in all the animals of Group 1, in which probatory excision was made, was 22.2.

The average percentage of metastases in the animals of Group 2, in which the tumors were removed without previous incision, was 21.8.

In the animals in Group 3, which were allowed to go without any operative procedure, the percentage of metastases was 32.2. These figures include metastases in the lungs and in the axillary, superior mediastinal, mediastinal, and peritoneal lymph-nodes.

Control Series 3 shows that the frequency of metastasis is a function of the time that the tumor remains in the body, and again emphasizes the well known fact that a malignant tumor should be removed as soon as possible after the diagnosis is made.

A similar experiment with the Crocker Fund rat sarcoma No. 10 on 384 animals also showed no increase in metastasis as a result of the incision of the tumor.

CONCLUSIONS

It is evident that this experiment demonstrates that in white rats bearing the Flexner-Jobling rat carcinoma, or the Crocker Fund rat sarcoma No. 10, metastasis is not increased when the tumor is incised, a fragment removed aseptically, and the growth allowed to remain in the animal for from ten to twelve days thereafter.

It permits the deduction, also, that human tumors are probably not widely distributed by incision, as has been thought, and that, therefore, when these tumors are situated in such portions of the body that a mutilating or highly dangerous operation is necessary for their removal, they should be examined microscopically if a diagnosis can be made in no other way.

It is preferable that such diagnosis be made immediately by frozen section, if facilities are available, so that if necessary the operation can be continued under the same anesthesia; but the patient's future is not necessarily compromised if a small fragment is removed, the wound closed, and the operation proceeded with the moment a microscopic diagnosis is obtained. With modern rapid methods of preparation of sections, the lapse of time need not be more than three or four days.⁷

Clinical Notes, Suggestions, and New Instruments

THE REMOVAL OF FOREIGN BODIES FROM THE TISSUES BY THE USE OF TRANSLUMINATION

A. G. BETTMAN, M.D., PORTLAND, ORE.

The difficulty often encountered in attempting to remove foreign bodies from the tissues is well known. Even when roentgenograms are at hand or when fluoroscopy has been done, there is frequently great difficulty in removing the foreign body.

By the use of translumination, any foreign body that will cast a shadow may be located in a surprisingly short time.

Having cut down to the supposed location of the foreign body and having arranged the light, the operator looks through a tube at the tissues, which may be held up or otherwise suitably manipulated. A dark room is unnecessary. When once the foreign body is located, it is a simple matter to remove it. Reference to the illustration will make the method clear.

Method of locating and removing foreign bodies from the tissues by the use of translumination.

The tube may be of any suitable material, brass or other metal or a darkened test tube; a roll of paper may be used in an emergency.

The angle at which the tube is used may be varied to meet conditions. Even deeply embedded material may be located frequently without the necessity of putting the end of the tube into the wound.

HOW TO MAKE EVEN POOR ADHESIVE PLASTER ADHERE

A. L. SORESI, M.D., NEW YORK

During the war we were confronted with numerous compound exposed fractures that needed continuous traction, and traction was made exceedingly difficult in many cases for two reasons: The skin was badly inflamed, being traumatized in most cases so that the areas of healthy skin to which to stick the plaster were very scanty, and this was aggravated by the fact that some of the wounds, being badly infected, had an abundant secretion that would soak the plaster and diminish its sticking qualities. Also, the adhesive plaster was at times of very poor quality.

We resorted to a simple plan, which can be employed easily and conveniently in all cases requiring medication with adhesive plaster. We took the common rubber cement that is used in patching tires, diluted it in about ten parts of ether, and painted the area of skin on which we intended to apply the plaster with it and then applied the plaster in the usual manner, after having cleaned and dried the skin. Even the poorest plaster adhered immediately and remained adherent for a long time. If the secretion was very abundant,

we painted with the same rubber solution the outside of the plaster after the plaster had been applied, so as to make the cloth waterproof by the application of a thin coat of rubber. Incidentally, it may be stated that the same rubber solution with ether has been applied to the skin in order to prepare it for operation, instead of tincture of iodine, with very satisfactory results.

The reason adhesive plaster adheres better if the skin is painted with a solution of rubber is that the solution of rubber and ether adheres strongly to the skin, and naturally the adhesive plaster will in its turn adhere firmly to the rubber that covers the skin.

A METHOD OF MOUNTING ANATOMIC AND PATHOLOGIC SPECIMENS IN GELATIN

KELLEY HALE, M.D., WILMINGTON, OHIO

The method here described is one by means of which specimens may be mounted between glass plates of any desired thickness or any size, depending on the character of the specimens.

1. The plates of glass are separated by strips of glass of any desired thickness. The strips should be one-half inch wide for ordinary work. For small or larger specimens, narrower or wider strips should be used.

2. Strips with square ends are cut the desired length by employing a piece of glass, the width of which is exactly equal to the length of the strips desired. An ordinary glass cutter and a draftsman's right angle rule or triangle are all that are required.

3. The strips are broken by holding the piece of glass in the left hand with the cut line down; then with a few swift, sharp strokes of the reverse end of the glass cutter, the glass opposite the cut line is fractured, and the strip is easily removed. As many strips as are needed may be cut.

4. The strips are then attached to the margins of the glass plate by means of Canada balsam from which the volatile principles have been driven off by heat. Optical houses can provide this material in stick form. A burning set employed by storage battery men is very effective in attaching the glass strips. A strip should be left out at one end.

5. The specimen or specimens are then attached to the plate by means of warm gelatin, in any position desired. They are kept in a horizontal position until the gelatin sets; then the plate with the specimens is immersed in liquor formaldehydi in order to render the gelatin insoluble and thus prevent the slipping of the specimen when mounted in warm gelatin.

6. Next the exposed side of the specimens is covered by attaching a glass plate to the glass frame with the volatilized Canada balsam.

7. After this the mounting process is finished by setting the glass case, with its contained specimens, in warm water. Liquid gelatin of any desired consistency is poured by means of a funnel into the glass case through the end that has been left open. The warm water prevents the gelatin's setting until all of the spaces have been filled and the air bubbles forced to the top of the gelatin. If the colors of the specimens have been preserved by Kaiserling's method, a jelly is prepared by adding gelatin, ten parts by weight to the third solution in which the specimens ordinarily are kept: water, 900 c.c.; glycerin, 540 c.c.; sodium acetate, 270 gm. A 1 per cent. solution of phenol (carbolic acid) is used for a preservative.

The gelatin should stop at a line corresponding to the inner edge of the glass strip that will be sealed in the end after the gelatin has solidified, and the exposed portion rendered insoluble by immersion in liquor formaldehydi. With care the glass case can be rendered air tight by closing the end with a strip of glass and the Canada balsam (stick).

8. Specimens can be labeled in a very simple manner. After the specimen is attached to the glass as described, the glass cover is placed in accurate position. With pen and drawing ink, ruled lines are drawn to parts that are indicated

in printed letters. The cover glass is then removed and the inside thoroughly cleansed and the ruled lines and names traced through the glass with water-proof ink. Fine lines can be made by using black silkworm gut attached to the inside by means of thick gelatin. The lines and names are much plainer after they have been transferred to the inside of the cover glass. This is true, too, of the specimens when viewed through glass. They are mounted as described before.

ADVANTAGES

1. This method does away with large containers, such as bottles and jars, for small specimens.

2. It is very difficult to see a specimen in a bottle, and it is impossible to study it without taking it out, which will often lead to destruction. With this method the specimen is immobilized between two glass plates, is plainly visible and can be carefully studied without danger of destruction.

3. This rendering delicate specimens, such as embryos and biologic material, indestructible makes this method a great time saver to the instructor who wishes to use such material for teaching purposes, as he can use this material year after year without fear of having it destroyed.

4. Preservation of cross-sections of embryos, developmental stages of fishes, tadpoles, sections of brain, injected, etc., can be had with the utmost satisfaction.

5. Specimens can be filed away classified like lantern slides.

6. By using plate glass, even sections of the adult human being can be preserved.

7. Specimens preserved in Kaiserling's solution can be mounted in this way and kept without losing their color.

8. This method can be used for displaying commercial products as well.

9. The specimens can be projected on the screen like any opaque objects, thus making it possible to use material at scientific meetings that could not be used otherwise.

New and Nonofficial Remedies

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

W. A. PUCKNER, SECRETARY.

CULTURE-LAC.—A culture of *Bacillus bulgaricus* in which marketed in bottles containing about 4 fluidounces.

Actions and Uses.—Culture-Lac is adapted both for internal and external use. See general article, Lactic Acid-Producing Organisms and Preparations (New and Nonofficial Remedies, 1919, p. 155).

Dosage.—From 4 to 8 Cc. (from 1 to 2 fluidrachms) in sweetened water one-half hour before meals. For infants 4 Cc. (1 fluidrachm) every two or three hours as directed by the physician. The date of issue is stated on each bottle.

Manufactured by the Geck Laboratory, New York. No U. S. patent. U. S. trademark applied for.

Maggots in the Ear.—A full blooded Indian, aged 21, came to my office one evening, stating that on the previous afternoon a fly lit on his cheek, that he brushed it away but knocked it into his ear, and it crawled into the auditory canal. He tried to dislodge it but was unable to do so, although he thinks it flew out again in a few minutes. At 3 o'clock the next morning he was awakened by a severe earache, and later his wife got fourteen maggots out of his ear. On examination I saw moving about—and easily extracted—some maggots with small forceps. I then washed out the ear with boric acid solution and obtained at least seventy-five more maggots. They were about 2 mm. in length, and quite thin. The patient had no further trouble.—OTTO H. G. ROSENKRANZ, M.D., Hoopa, Calif.

ANOXEMIA, OR OXYGEN DEFICIENCY, AND ABNORMAL RESPIRATION IN CERTAIN DISEASES

It commonly happens that when an important discovery is made in some field of science, as for example when a cause for a familiar phenomenon is ascertained, attention is at once diverted toward this to the exclusion of all other explanations or possible contributory causes. This has been the experience in the study of the regulation of respiration. Fifteen years ago the nervous mechanism of regulation, particularly the so-called Hering-Breuer reflex, was the predominant feature of all discussions of respiratory function. No sooner, however, had Haldane and Priestley¹ given their classic demonstration, in 1905, of the fundamental dominance of chemical factors in the control of breathing than they became the center of interest. Although in the earlier days the stimulus to augmented respiration was sought in a lack of oxygen, it has been recognized for some time, as the result of Haldane and Priestley's work, that ordinarily the respiration is regulated with the utmost delicacy in correspondence with the carbon dioxide tension of the blood passing through the respiratory center; and it is now the generally accepted opinion that what the center actually responds to is increased hydrogen ion concentration.

Largely owing to further investigations of Haldane and his English collaborators,² the effects of a shortage of oxygen are known as well as the response to accumulating carbon dioxide. Whereas the latter increases the depth of respiration and the pulmonary ventilation without essentially altering its rate, the effect of want of oxygen is to increase the rate rather than the depth. When the anoxemia, or deficiency of oxygen in the circulating medium, becomes pronounced, the respiratory center may give rise to a peculiar periodicity of the breathing. Finally, when the proportion of oxygen is still further reduced, this effect may be replaced by a very rapid, shallow type of respiration. Haldane, Meakins and Priestley point out that in such condi-

tions a very dangerous vicious circle tends to be set up. Want of oxygen in the inspired air causes shallow breathing, which in turn intensifies the anoxemia. There are variations in the mode of response of different persons. In some, a lowered threshold for stimulation by carbonic acid results in a hyperpnea that tends to postpone the dangerous effects of oxygen want by the increased efficiency of the lung ventilation. The English investigators maintain that those who react to want of oxygen preeminently by shallow breathing will be more seriously affected under conditions of lowered barometric pressure than those whose reaction involves a great alteration of carbonic acid threshold. This, they add, would seem to afford an explanation of the much greater liability of some persons over others to mountain sickness and aviator's disease.

In war-time studies of patients suffering from what is frequently designated as "irritable heart," "soldiers' heart" or "effort syndrome," at the Duchess of Connaught's Red Cross Hospital, Haldane, Meakins and Priestley³ have found that in addition to breathlessness on exertion, rapid pulse, exhaustion, fainting attacks and irritability, these sick invariably show a remarkable type of breathing. The respiration is rapid (from 20 to 60 or more per minute) and shallow (250 to 350 c.c. or thereabouts), and, on exertion, the rate increases very abnormally while the increase in depth is abnormally small. These effects are strictly comparable to the symptoms already described for intense anoxemia. The correspondence is confirmed by the observation at the army hospital that, when they are breathing oxygen, the patients are able to do an amount of muscular work that is quite beyond their powers when they breathe air only, and they state emphatically that the oxygen relieves their subjective symptoms.

Special experiments conducted by Haldane and his army collaborators have, indeed, shown that abnormal shallowness in breathing (such as is so often observed in cases of irritable heart) causes uneven ventilation of the lungs. This in turn brings about anoxemia and consequently periodic respiration and other symptoms, as has been explained. Abnormality of breathing of the shallow, quick type points to a deficiency of oxygen, just as deepening of respiration suggests accumulation of carbon dioxide in the organism. Whether the anoxemia is attributable to impairment of the circulation or to factors which prevent adequate lung ventilation, the indication for immediate relief is the same. Imperfect oxygenation may arise, as Haldane and others³ have pointed out, in any condition such as bronchitis, asthma or emphysema, in which the even distribution of air in the lungs is hindered by local narrowing of bronchi or local impairment of the lung elasticity. They add that when shallow breathing,

3. Haldane, J. S.; Meakins, J. C., and Priestley, J. G.: The Effects of Shallow Breathing, *J. Physiol.* 52: 433 (May 20) 1919.

resulting as a secondary nervous effect of the anoxemia, is superposed on the mechanical hindrance to even distribution of air, the anoxemia must become much more serious. An entirely new light is thus thrown on the symptoms. In any event, oxygen therapy thus comes into a new prominence.

ARTIFICIAL PNEUMOTHORAX

During the twenty-five centuries that have elapsed since Greek, and possibly Hindu, physicians cured tuberculosis by rest and a proper diet, at least two things of real value have been added to the treatment: more rest and more attention to the diet. The phthisio-therapist must be an optimist. Given suitable economic conditions that enable him to enforce his regimen of rest and diet, he can frequently make a favorable prognosis. Certainly few infectious diseases offer the body a greater opportunity for successful resistance than does tuberculosis. The wisdom of the policy of noninterference has become so generally recognized that we are today perhaps overcautious and too conservative in our judgment of procedures that savor of active intervention. Among these is the use of artificial pneumothorax. Developed as an adjunct of rest therapy, it offers, in its ideal utilization, the utmost that we can expect from absolute rest.

Aside from the reluctance to depart from the policy of letting well enough alone, there is an impression among many physicians that the procedure is dangerous. Untoward results, however, have been limited virtually to the cases in which too large amounts of gas have been injected at the early fillings. These larger amounts of gas have been given on the false assumption that if a little gas is good, more will be better. Forlanini himself, in his first publications, warned against the use of large amounts of gas. He limited the amount injected at any one sitting to from 100 to 300 c.c., but the early advocates of his method in this country (Murphy) and in Germany (Brauer) used larger amounts with admittedly spectacular but occasionally unfortunate results.

Murphy, however, laid great emphasis on the use of artificial pneumothorax earlier in the course of the disease. Then its effect might be assumed to be curative rather than merely palliative, as is so frequently the case when used in tuberculous patients in the utterly hopeless terminal stages of the disease. There is much to justify this position. Since pleural adhesions are the chief factor in the nonsuccess of the method, we should seek to apply the pneumothorax at a time when such adhesions are likely to be less frequent. They are found commonly enough in the routine postmortem examination of bodies that present otherwise normal lung findings. In cases of tuberculosis, in which the rich lymphatic network of the visceral pleura is so often the site of early extension, fibrinous and fibrous adhesions can be taken for granted

in practically every case. The earlier the pneumothorax is attempted, the less likely it will be that adhesions will prove too extensive for favorable collapse therapy.

The end-results of treatment described by Beggs,¹ Minor,² Morris,³ and Kendall and Alexander⁴ seem to warrant definite confidence in the usefulness of the method in cases that are advancing despite the ordinary regimen of rest and diet, and perhaps also in early cases in which, because of unfavorable economic conditions, we cannot be assured that the patient will have the advantages (or at least the maximum benefit) that are possible under the usual hygienic and upbuilding methods.

It has been found in actual practice that the theoretical advantages of collapse therapy are fulfilled to a large degree, even when we cannot be certain that we have attained a complete result. The relative bloodlessness and the stasis of the lymph currents of the collapsed lung are followed by a lessening of the toxemia because of the decrease in the absorption of toxic material; the chances for dissemination of the infection are diminished; the rest accelerates cicatrization. To be weighed against these advantages is the possibility of activating a dormant focus of the opposite lung on which the entire task of ventilation is imposed. In hemorrhage, occasionally in lung abscess, and in some cases of bronchiectasis, ordinary contraindications must frequently be disregarded in view of the mechanical benefits of immediate compression and the relief thereby gained.

Artificial pneumothorax is today a relatively safe procedure. With gas injected under aseptic precautions, controlled by the roentgen ray and the manometer, and given in the small amounts insisted on by every conscientious worker, few complications need be feared. At present the method is seldom used except by the specialist in the tuberculosis field. The vast majority of tuberculous patients, however, are treated not by specialists but by the general practitioner, and there is no valid reason why a safe remedial measure should be withheld from the patient, who not infrequently is seen at a time when the pleural conditions are still favorable for the successful use of the pneumothorax.

If soldiers can be kept on active duty with a pneumothorax that is refilled at definite intervals, as they have been in the French army, there is no reason why, in times of peace, we cannot keep many patients in active, normal life and gaining a livelihood at their usual occupation. Under such conditions we are more likely,

1. Beggs, W. N.: Induced Pneumothorax in Pulmonary Tuberculosis. *Am. Rev. Tuberc.* 1: 509 (Nov.) 1917.

2. Minor, C. L.: Deductions from Four and One-Half Years' Use of Artificial Pneumothorax in the Treatment of Pulmonary Tuberculosis. *Am. Rev. Tuberc.* 1: 522 (Nov.) 1917.

3. Morris, Everett: Induced Pneumothorax: Its Use in the Treatment of Pulmonary Tuberculosis, with Report of Two Hundred and Two Cases. *Am. Rev. Tuberc.* 2: 485 (Oct.) 1918.

4. Kendall, W. B., and Alexander, C. C.: Clinical Report on One Hundred and Thirty-One Cases Treated by Artificial Pneumothorax. *Am. Rev. Tuberc.* 2: 79 (April) 1918.

also, to keep the lung compressed for a longer period of time than if the patient is treated for a relatively short term at some institution and returns then to his former environment without further supervision. Keeping in mind the fact that collapse therapy is really rest therapy, Morris has well emphasized that it is much safer to keep a lung compressed too long than not long enough.

NEW LIGHT ON PULMONARY EDEMA FROM STUDY OF THE LETHAL WAR GASES

The lethal gases about which so much has been heard since they were first introduced into modern warfare in an extensive way are respiratory irritants. They produce a pulmonary edema, along with congestion and a series of symptoms that are either caused by the pulmonary condition or are concomitant with it. Obviously, the rational treatment of gas poisoning depends on a clear understanding of the factors that are concerned in these varied symptoms; and consequently much attention was devoted by the scientists of the allied governments during the war to unraveling the mysteries of the pathology of gas poisoning. In his Harvey Lecture, Underhill¹ has disclosed new facts of prominent interest elicited through the extensive investigations of the Chemical Warfare Service of the United States Army. According to these, in addition to pulmonary edema, "gassing has a definite influence on the respiration, heart beat, temperature, the concentration of the blood, the water content of the lungs and other tissues, the chlorid content of the blood and tissues with resulting changes in chlorid excretion by way of the kidneys, the number of the red and white cells of the blood, and the respiratory function of the blood, leading to dyspnea and partial asphyxia. Acidosis is present at times, and there is a distinct influence on protein metabolism."

Since little or none of the harmful gas is absorbed, as a rule, the detrimental influence, Underhill insists, must be explained by an interpretation of the effects induced in the respiratory tract. Novel and distinct are the changes in the concentration of the blood. Sooner or later the latter is increased along with the development of the edema which induces the withdrawal of fluid from the circulating medium and its transfer to the lungs. The decrease in the blood volume helps to explain some features of the impaired circulation occasionally noted.

Heretofore it has been tacitly assumed that death from gas poisoning is due directly to the pulmonary edema. The experts of the Chemical Warfare Service have, however, taken exception to this view in some measure. Underhill¹ has performed a distinct service in calling attention to the blood concentration as more

likely to produce death than is the presence of fluid in the lungs. Obviously, the edema is the cause of the blood concentration and therefore is ultimately responsible for the untoward consequences. However, the asphyxiating effects of the fluid in the lungs can be overcome by the administration of oxygen until the blood is arterIALIZED, yet death intervenes as usual. On the other hand, it has been shown that when the blood is restored to a more normal concentration by infusion of physiologic sodium chlorid solution, the gassed individual may survive even though an extensive edema exists.

The fact that the control of the concentration of the blood, so that it becomes restored to something approaching its normal condition, plays a determining part in the chances for recovery, in cases in which pulmonary edema exists, deserves a wider recognition. It is one of the lessons of war-time scientific medical research. Administration of oxygen may supplement the value of the infusion of physiologic sodium chlorid solution by preventing anoxemia. Underhill has pointed out that oxygen treatment alone does not strike at the fundamental difficulty as it was once supposed to do. Oxygen starvation is induced by an inadequate circulation for which concentrated blood may be responsible quite as well as poor ventilation through an edematous lung. Hence, in such conditions, measures must be taken to restore the blood to a concentration at which life is possible.

Sometimes blood dilution occurs in the first stage of poisoning with gases, as happens with phosgen. In these cases, venesection is indicated. The composition of the blood must never be lost sight of, since it seems to furnish the key to successful remedial therapy in which infusion and oxygen administration may have a significant part.

BENZYL BENZOATE: THE STORY OF A PROMISING RESEARCH IN THERAPY

So many of the procedures still employed in present-day therapy are veiled in the mysteries of traditional effects or empiric judgments that there is fascination in the story of any drug or remedial measure that has a logical demonstration of pharmacologic potency in its history. Although the benzyl esters have been known only a short time in medicine, the possibilities of their usefulness in a rational way in certain fields of practice is becoming apparent. Benzyl benzoate has already been accepted for publication in New and Nonofficial Remedies, of the Council on Pharmacy and Chemistry. The suggestion of the applicability of the benzyl esters in therapy arose from Macht's studies of the opium alkaloids. These investigations disclosed the fact that whereas opium and its alkaloids exert their most marked effects on the central nervous system, they also have unmistakable influence on peripheral structures, notably the smooth muscle organs.

¹ Underhill, E. P.: The Physiology and Experimental Treatment of Poisoning with the Lethal War Gases, *Arch. Int. Med.* 23:753 (June) 1915.

A systematic examination of the individual opium alkaloids—the logical sequence of the observations just mentioned—demonstrated that these chemical substances can be divided into two classes: the pyridin-phenanthrene group, of which morphin is the prominent representative, and the benzyl-isoquinolin group, to which papaverin belongs. The former was found to stimulate contractions of unstriated muscle, whereas the papaverin-like alkaloids inhibit the contractions and lower the muscle forms.

Macht and his co-workers did not stop with the proof of these differentiating effects. The difference in chemical structure between the two antagonistic types of opium alkaloids suggested the search for simpler, non-narcotic compounds which might still act in an inhibitory manner on smooth musculature. As a result, the discovery that benzyl benzoate and benzyl acetate behave like papaverin toward the unstriated muscles was made.

The low toxicity of these drugs, combined with their peculiar pharmacologic action, suggested the possibility of usefulness in conditions under which spasm of smooth muscle must be counteracted. Ureteral colic and excessive intestinal peristalsis have already been shown to yield to the tonus-lowering, antispasmodic effects of both compounds. Something of the history of the studies in this field has been recorded in a recent number of *THE JOURNAL*.¹ In this research, the laboratory and the clinic have combined to institute a step in therapeutic progress that promises beneficent results.

Current Comment

SOME ASPECTS OF THE HYPOPHYSIS AND SUGAR METABOLISM

An abundance of experimental and clinical evidence tends to indicate that the pituitary structures may in some way be concerned with carbohydrate metabolism in the body. One may recall the asserted increased tolerance for carbohydrates in well marked cases of acromegaly and in persons suffering from pituitary tumors. On the other hand, stimulation of the hypophysis in animals causes an unmistakable hyperglycemia. What happens in these varied circumstances remains to be elucidated. Some investigators have postulated the liberation of a hormone from the hypophysis when it is stimulated; and this hypothetic chemical product has been held responsible for the metabolic effects in respect to sugar utilization, just as pituitary extracts are known to have effects on muscular structures. Others have regarded the changes in the level of blood sugar after pituitary involvement as the expression of nervous impulses. As one investigator has expressed it: "It appears that excitation of the hypophysis has originated a stimulus which is

directed peripheralward by nervous connections and falls on the splanchnic-adrenal-hepatic mechanism controlling the ultimate partition of glycogen." Keeton and Becht² of Chicago have noted that hyperglycemia commonly associated with pituitary stimulation is absent after transection of the spinal cord and after section of the splanchnics. Hence the view is favored that, in this case at least, the pathway of relation between hypophysis and carbohydrate mechanism is a nervous one through the splanchnic nerves to their terminations in the suprarenals and the liver. If a hormone is liberated by stimulation of the gland, they add, it must have a central action; otherwise nerve section would not prevent it from reaching the sugar-transforming organs. The Chicago investigators also believe that the physiologic rôle played by the hypophysis in carbohydrate metabolism is concerned, not with the transformation of glycogen to sugar, that is, glycogenolysis, but more probably with the utilization of sugar by the organism.

THE RELATION OF INSECTS TO DISEASE

Demonstration of the share of certain insects in the causation of disease constitutes one of the most brilliant chapters in the unparalleled record of medical progress made since 1870. Conjecture has given way to assurance, supposition to verified fact. Most investigators probably believe that the greatest triumphs in this field have already been accomplished, and that the future hardly holds in store for us very many, if any, more such momentous discoveries as the connection between the mosquito and malaria and yellow fever, the flea and the plague, the louse and typhus. It is perhaps well to bear in mind, however, as W. D. Pierce has recently reminded us,³ that there are still numerous minor problems to be worked out and that cooperation and organization are especially desirable in this field. Although somewhat formidable in manner and matter, the sequence of "necessary steps" in Pierce's program contains an interesting statement of the point of view of certain entomologists. The emphasis laid on proper methods of handling experimental insects is certainly desirable. His remarks on the importance of cooperation by specialists in different fields will doubtless receive hearty approval. Some of his other suggestions seem rather cumbersome and inapplicable in the present state of our knowledge; such, for instance, as the proposal that "one might in time of an epidemic start with insects visiting excreta and attempt to ascertain whether the organism of the disease at that time epidemic occurs in any of the insects." Few investigators will maintain that the most important advances in our knowledge of insect-borne diseases have been due to procedures of this character. It is hard to believe that the author has given serious consideration to his statement that "the majority of the investigations which have been seriously undertaken to determine invertebrate carriers have been conducted on other continents than ours." We need only remind ourselves of the

1. Macht, D. I.: A Therapeutic Study, Pharmacologic and Clinical, of Benzyl Benzoate, *J. A. M. A.*, 73: 599 (Aug. 23) 1919. Litzenberg, I. C.: The Use of Benzyl Benzoate in Dysmenorrhea, *ibid.*, p. 601.

2. Keeton, R. W., and Becht, F. C.: The Relation of Hypophysis to Glycogenolysis, *Am. J. Physiol.*, 49: 248 (July 1) 1919.

3. Pierce, W. D.: Necessary Steps in Any Attempt to Prove Insect Transmission as Causation of Disease, *Science*, Aug. 8, 1919, p. 122.

pioneer work of Theobald Smith on Texas fever, the memorable discovery of the rôle of the mosquito in yellow fever, the work of Ricketts and others on typhus and Rocky Mountain spotted fever, and the recent work of the U. S. Public Health Service on malaria carriers, to see that such an assertion is hardly an adequate recognition of the part played by American men of science in this field.

DID YOU ORDER A HUNDRED-DOLLAR REBUILT FORD?

Physicians in the Middle West have received a circular letter from the "Anchor Manufacturing Company" of New York City, signed "per E. Maloney." The letter declares that the concern is going to sell, to a limited number of "professional men," a "fine lot of Ford automobiles" that it has purchased from the U. S. government. They are used machines, "all 1917 or 1918 models," but have been thoroughly overhauled "by expert mechanics who have had their training in one of the Ford plants." The price asked is \$100, freight prepaid! Fifty dollars must be sent with order ("Liberty Bonds accepted at full face value") and the balance is to be paid after the car is delivered. All worn and defective parts of these cars have been replaced, the upholstery has been renewed, the car repainted, and refinished from top to bottom, fully equipped with new antiskid tires, new inner tubes, side curtains, tools and—an artistic touch—the purchaser would also get, without extra charge, a "manual on care of car with full instructions on driving." To lend an air of verisimilitude to what might otherwise seem to be a bald and unconvincing tale, Mr. Maloney stated that his company was, as an advertising proposition, "going to place twenty cars in that number of communities to which we can refer prospective customers." Their reason for picking out—or should we say "picking on"—doctors was that a "professional man knows and is known by more persons in his locality than any other citizen." The Anchor Manufacturing Company's stationery was somewhat imposing, being, in fact, a rather skilful imitation lithographed letter-head. The company gave as a reference the Chatham and Phenix National Bank of the City of New York, but insisted that all remittances be made payable to the Anchor Manufacturing Company. An Iowa physician, however, was wise; he decided to test out the proposition and sent his check for \$50 to the Chatham and Phenix National Bank, telling that institution to forward his letter, money and order to the concern if the company was responsible. In a short time the doctor got his check back with a statement by the Chatham and Phenix National Bank to this effect:

"The Anchor Manufacturing Company referred to us without permission and we have nothing on file to justify an opinion."

After receiving letters from several physicians, indicating that the scheme was being extensively worked, THE JOURNAL telegraphed its New York representative to look into the matter. He reports that, according to the renting office of the building in which the "Anchor Manufacturing Company" had desk room, Mr. Maloney had left somewhat hurriedly four days previ-

ously, just about an hour ahead of a call from the New York Police Department. Further, it seems that numerous telegrams and long distance messages have been coming in recently to the renting office of 51 East Forty-Second Street, inquiring about the standing of the Anchor Manufacturing Company, all of which may indicate that a number of doctors are "out" a fifty dollar Liberty Bond or a check for that amount. To the shrewd business man the proposition made by the "Anchor Manufacturing Company" is preposterous on its face—but we members of the medical profession are not shrewd business men. Never has there been a time in which the get-rich-quick promoters have been more active than today. It behooves physicians to examine with more than ordinary care the proposals whereby they are offered returns out of all proportion to the investment required.

Medical Mobilization and the War

Personnel of the Medical Department

For the week ending August 29, there were 7,535 officers in the Medical Corps, a decrease of 631 from the previous week. The Medical Reserve Corps contained 3,310. The total number of physicians discharged since the beginning of the war is 24,580.

Bulletin for Air Medical Service

Authority to publish a *Bulletin of the Air Medical Service* is asked of Congress by the Secretary of War in a recent executive communication. In requesting this authority the Secretary said: "The Director of the Air Service states that as a result of the studies and experiments made by the medical officers on duty with the Air Service, especially those at the Medical Research Laboratory, much valuable information is now ready for publication. It is necessary that medical officers attached to the air service be kept in constant touch with developments in this new and important phase of aviation. Developments are so rapid and so much information is coming in that it is not considered in the best interest of the service to embody such information in a book, as such a book would require frequent revision." The publication would be published quarterly.

Investigation of Walter Reed Hospital Asked

A resolution directing the immediate investigation of Walter Reed Hospital and St. Elizabeth's Hospital, both at Washington, D. C., operated under the Medical Department of the Army, has been introduced by Congressman Charles J. Thompson of Ohio, in the House of Representatives. The resolution recites that complaints as to the conduct of these hospitals and of great cruelty therein have been made by those confined therein. The resolution has been referred to Select Committee on Expenditures of the House for consideration.

HONORABLE DISCHARGES, MEDICAL CORPS, U. S. ARMY

NOTE.—In the following list, L. signifies lieutenant; C., captain; M., major; L. C., lieutenant-colonel; and C., colonel.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATIVE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

ALABAMA

Hospital News.—The Eliza Coffee Memorial Hospital, built by the citizens of Florence, was opened to receive patients, August 8. The institution will accommodate thirty-two patients, and will be in charge of Dr. Luther T. Young. The New Tennessee Coal, Iron and Railway Company Hospital, Fairfield, is practically ready for occupancy. This hospital has been built for the employees of the company and their families, and has a capacity of 350. Dr. Lloyd Noland, Birmingham, chief surgeon of the company, is in charge of the institution.

Personal.—Lieut.-Col. Seale Harris, Birmingham, is at present ill in the Walter Reed Hospital, Washington, D. C., with phlebitis of one of the veins of the foot. He will probably return to Birmingham about October 1.—Dr. Cecil D. Gasten, municipal physician of Birmingham, has been appointed assistant surgeon in charge of the Norwood Infirmary.—Dr. William M. Faulk, Tuscaloosa, has been appointed assistant superintendent of the Alabama Insane Hospital.—Dr. George H. Searcy has been appointed local surgeon of the Alabama Great Southern Railway; Dr. Thomas H. Patton, assistant surgeon of the Louisville and Nashville Railway, and Dr. Maxwell Moody, local surgeon of the Mobile and Ohio Railway, all at Tuscaloosa.—Dr. T. Brannon Hubbard has resigned as physician in charge of the Social Disease Clinic of Montgomery, and has taken charge of the Highland Park Sanitarium; Dr. James R. Haigler, Montgomery, has been appointed his successor.

CALIFORNIA

Personal.—Dr. George W. Corner, III, Berkeley, has resigned as professor of medicine in the University of California, to accept an assistant professorship in his alma mater, Johns Hopkins University, Baltimore.—Dr. Harold W. Wright, San Francisco, has recently been demobilized from service after two years in the neuropsychiatric division.

New Appointments and Promotions at University.—The following appointments and promotions have recently been made at Stanford University Medical School for the year of 1918-1919.

Medicine: M. J. Desires, lecturer on physical therapy; G. E. Farrington, lecturer on speech defects; H. C. McCrehan, lecturer on medicine (pediatrics); Peter H. Luttrell, clinical instructor in medicine; N. A. Sells, clinical instructor in medicine (electrotherapy); Obstetrics and Gynecology: Frank B. Compton, lecturer on gynecology; William R. Stevens, lecturer on medicine.

Surgery: Harry A. Brown, clinical instructor in surgery (ophthalmology); Robert P. O'Connor, clinical instructor in surgery; Sterling Bennett, lecturer on surgery; George W. Ortman, lecturer in pediatric surgery; Harry A. K. Hixson, lecturer on surgery; G. L. P. Wells, lecturer on surgery (otology, otolaryngology, laryngology); Earl S. Stevens, lecturer on surgery; Alfred J. Zerk, lecturer on proctology.

Assistant Medicine: Clement H. Arnold, assistant in medicine; J. A. Danne, assistant in medicine (dermatology); Norbert J. Galt, Jr., assistant in medicine (oncology); Harry Sprui, assistant in medicine; William E. Smith, assistant in medicine.

Obstetrics and Gynecology: Frank B. Galbraith, assistant in obstetrics and gynecology.

Surgery: H. W. Duffley, assistant in surgery (ophthalmology); Samuel N. Jacob, assistant in surgery; Leonard Raynes, assistant in surgery; Joseph D. King, assistant in surgery (genitourinary); John I. Campbell, clinic dentist.

Promotions.—Walter W. Boardman, from assistant professor to associate professor of medicine (radiography); George D. Emmet, from instructor to a full clinical professor of medicine; William R. P. Clark, from clinical instructor to assistant clinical professor of medicine (tuberculosis); Michael M. C. Gray, from clinical instructor to assistant clinical professor of medicine (pediatrics); M. Monica Dunn, from clinical instructor to assistant clinical professor of medicine; W. H. Church, from clinical instructor to clinical instructor in surgery; Maude N. Haver, from clinical instructor to clinical instructor in medicine; Leo Elasser, from assistant clinical professor to assistant clinical professor of surgery; Theodor C. Felt, from clinical instructor to assistant clinical professor of medicine (dermatology); William Kenney, from assistant to clinical instructor in medicine (oncology); Lester O. Kimball, from assistant to clinical instructor in surgery; Harry L. Engemann, from clinical instructor to a full clinical professor of surgery (dermatology); Mary C. Raynor, from assistant to clinical instructor in medicine (pediatrics); Harry G. McIntosh, from clinical instructor to assistant clinical professor of medicine (oncology); Philip H. Pearson, from assistant to clinical instructor in medicine (dermatology); Pax Marion Reed, from a student to clinical instructor in medicine; Alfred C. Reed, from clinical instructor to assistant clinical professor of medicine;

Karl L. Schaupp, from assistant to clinical instructor in obstetrics and gynecology; Otto A. Sharpe, from assistant to clinical instructor in surgery (ophthalmology); Roland B. Tupper, from clinical instructor to assistant clinical professor of medicine; Jean R. Oliver, from associate professor of pathology.

DISTRICT OF COLUMBIA

Commissioners of District to Have Increased Public Health Powers.—A bill to enlarge the powers of the commissioners of the District of Columbia relative to public health affairs has been introduced in the House by Congressman Carl E. Mapes, chairman of the House District Committee. The measure empowers the district commissioners to make and enforce such regulations as they may deem proper from time to time to prevent the spread of contagious, communicable and infectious diseases, which regulations may authorize compulsory reports and testimony in court by physicians and surgeons and by superintendents of public hospitals and managers of private hospitals and the examination of persons suffering from such diseases. Provision is made for proper publicity of new regulations. The measure is H. R. 8056 and has been referred to the Committee on the District of Columbia for action. It is indorsed by the commissioners of the district.

FLORIDA

Personal.—Lester J. Eiford, Lieut.-Col., M. C., U. S. Army, Tampa, has returned after ten months of overseas service, during which he was in command of a base hospital at Nantes.

Board Adopts Retrenchment Policy.—The state board of health, at its meeting in Jacksonville, August 7, adopted a policy of retrenchment which it believes will enable it to accomplish the widest and most effective service. The staff of district health officers was cut in half, from eight to four, and the state was redistricted in accordance with the congressional districts. The board intends to concentrate much of its energies on venereal disease problems, and open free clinics at labor centers throughout the state. The child welfare and venereal disease headquarters will be moved from Tampa to Jacksonville, and the laboratory formerly conducted by the board in Tallahassee will be reopened.

ILLINOIS

The Misuse of Opium and Its Derivatives.—The health commissioner of Chicago states that physicians of the city in one month gave more than 103,000 prescriptions containing opium or its derivatives to be employed in the treatment of influenza.

Pharmaceutical Medal Awarded.—The Remington Medal, given annually to a member of the American Pharmaceutical Association who makes the most notable contribution toward the advancement of pharmacy, was awarded to Prof. James P. Beal, dean of the College of Pharmacy of the University of Illinois, Chicago, at the sixty-seventh annual meeting of the American Pharmaceutical Association held in New York City.

INDIANA

Diphtheria in Richmond.—Investigation of the local outbreak of diphtheria at Richmond was, it is reported, due to the eating of ice cream from a plant in which two employees had been suffering from some disease of the throat which is believed to have been diphtheria.

Personal.—Dr. Alexander Johnson, formerly head of the Feebleminded Institute of Indiana, at Fort Wayne, and for the last four years field worker for the National Society for the Prevention and Cure of Feeble-Minded, has been appointed superintendent of the Milne Home School for Girls, the industrial home for feebleminded women, New Orleans. The home was opened to receive inmates, August 18.—Dr. David P. Caldwell, Indianapolis, left, August 28, for Vancouver on his way to Batang, Thibet, where he will serve for seven years in the Thibetan Christian Mission.

MARYLAND

Personal.—Dr. Ralph Meyers has been appointed professor of pharmacology; Dr. Carl L. Davis, Washington, D. C., has been appointed professor of anatomy, in place of the late Dr. J. Holmes Smith, and Dr. William Carson von Glahn, Baltimore, has been appointed instructor of pathology at the Maryland University. The following physicians, who have been in the service during the past two years, will resume their classes in October: Archibald C. Harrison, Cary B.

Gamble, Arthur M. Shipley, Page Edmunds, Hugh W. Brent, E. A. Cooper, Frank Martin, G. Milton Linthicum, Henry J. Walton and Andrew C. Gillis. Dr. Harry Friedenwald, Baltimore, has recently returned from the Holy Land and will also resume his classes.

Large Enrolment of Students at Medical Schools.—Responding to the nation-wide appeal for young men to take up the study of medicine, many have enrolled at both the Johns Hopkins University and the University of Maryland. Classes in medicine will be larger this year than usual, according to announcements from the two institutions. The study of medicine at these two schools was handicapped to a great extent the last two years owing to several instructors being in the service and to enlistments of students. The professors have returned and the majority of the students who entered the service before graduating will resume their studies. The University of Maryland School of Medicine will have an enrolment of 275, it has been announced by Dr. James M. H. Rowland, Baltimore, the dean.

MASSACHUSETTS

Hospital Notes.—The Julia M. Moseley ward of the Anna Jaques Hospital, Newburyport, which is to be devoted to the care of tuberculous patients, was opened to receive patients, August 22. The hospital was erected by Charles W. Moseley at a cost of about \$40,000, and will accommodate sixteen patients. The temporary structure to be operated by Brooks Cubicle Hospital, on the summit of Corey Hill, Brookline, will be ready for occupancy early this month.

MICHIGAN

Personal.—Dr. Harvey E. Hoffman, for several years city physician of Ludington, has resigned.

Society Reorganized.—The Dickinson-Iron County Medical Society was reorganized at the meeting held in Crystal Falls, August 13, and Dr. William J. Anderson, Iron Mountain, was elected president, and Dr. Leslie E. Bovik, Crystal Falls, secretary. The next meeting will be held in Iron Mountain.

Location of Detention Hospitals.—It has been decided by the supreme court of Michigan, that a board of health cannot locate and maintain a detention hospital for the treatment of communicable diseases in a thickly settled residential district. In this case in which the decision was sought, a suit was brought to restrain the maintenance of a detention hospital in a residential district, by the board of health of Lansing.

MINNESOTA

Public Health Nursing.—September 1, the university course in public health nursing was opened at the University of Minnesota, Minneapolis. The course is to be the usual four months of inspection and field work, followed up by another four months' course either in repetition or in continuation of the study.

Personal.—D. Frank W. Mackoy, Mudbaden, has resigned as medical director of the Mudbaden Sanitarium, Jordan, to return to his former position as a member of the staff of the Sacred Heart Sanitarium, Milwaukee. Dr. Herbert O. Collins, Minneapolis, has been appointed superintendent of the State University of Iowa Hospital, Iowa City. Dr. Carl J. Holman, Mankato, underwent an operation, August 4, in Rochester, for gallbladder disease. Dr. Christopher Graham has severed his connection with the Mayo Clinic, Rochester, after twenty years of service, and has been succeeded by Dr. George B. Eusterman.

NEBRASKA

Medical Arts Building.—The plans for the new Medical Arts Building, Omaha, are practically completed and contracts are already being signed for floor space in the new building.

Personal.—Dr. James D. Case, superintendent of the State Hospital for the Insane, Lincoln, has, it is said, declined to turn over the superintendency of the institution to any one excepting the former incumbent, Dr. Lawrence B. Pillsbury, on his return from military service. Dr. Pillsbury, on his return, expects to enter private practice. The board of trustees has made the appointment of Dr. Case permanent. Dr. Benjamin F. Williams, Lincoln, has resigned as head of the state board of control. Dr. Emma Robbins, Hastings, who has been a medical missionary in China for five years, sailed on her return to her post of duty from San Francisco, August 23.

NEW YORK

Personal.—Dr. Wallace J. Herriman, Rochester, who has been in the Naval Militia since April, 1917, has been promoted to medical inspector, M. C., with the rank of commander. Dr. Anna M. Otto, Syracuse, started for Vancouver, August 21, and from there will sail for Ludhiana, India, as a medical missionary, September 4. Dr. Morris Bellin, Albany, has been appointed coroner's physician of Albany County, succeeded Dr. Fred C. Myers, deceased.

New York City

Personal.—Henry P. Davidson, chairman of the War Council of the American Red Cross, has received from Secretary of War Baker, in behalf of President Wilson, the Distinguished Service Medal for meritorious and distinguished services in behalf of the government and the American Red Cross during the war. Drs. Louis Aldrich Blake, Louisa Martindale and Marion Wright of England have arrived in this country to attend the world conference of women physicians to be held in this city beginning September 15.

New Plans for Care of Drug Addicts.—The project of using Sea View Hospital on Staten Island for the care and treatment of drug addicts has been abandoned because of the threatened injunction proceedings by civic organizations of Staten Island. The health department has now gone on with preparations for the use of Riverside Hospital on North Brother Island, which is under the control of the health department. In this institution 700 beds are now available for the use of drug users. Riverside has been vacated of all other patients and will be used exclusively for drug patients. Dr. Copeland states that \$75,000 will be required for the operation and maintenance of this hospital to the end of the present year.

NORTH DAKOTA

New Examining Board.—The governor, August 4, named Dr. John G. Arneberg, Grand Forks; Samuel A. Zimmerman, Valley City, and William G. Brown, Fargo, members of the state board of medical examiners for terms of three years, succeeding Dr. George M. Williamson, Grand Forks; Gustavus J. McIntosh, Devils Lake, and Joseph G. Dillon, Fargo, whose terms have expired.

Personal.—The School of Medicine of the University of North Dakota announces the appointment of Dr. Benjamin J. Clawson, Chicago, as professor of pathology, and of Dr. Arthur D. Bush, as professor of physiology. Dr. Arthur A. Whittemore, Bowman, has made a proposition that the cities of Bismarck, Jamestown, Valley City and Dickinson, unite in employing a whole-time health officer.

Venereal Disease in the State.—In the nine principal cities in North Dakota during the three months ending Aug. 30, 1919, 202 cases of venereal disease were reported, forty of which were in Minot and twenty-eight in Fargo. Full reports have not been received from the state clinics or from the physicians who are administering neo-arsphenamin on behalf of the bureau, but the records show that twenty-four doses of this drug have been administered. Of the 202 cases reported forty-six were of syphilis, 154 of gonorrhea and two of chancroid.

PENNSYLVANIA

Aims to Stop State's Gifts to Sixty-Six Hospitals.—Action in equity to restrain payment of state appropriations to sixty-six hospitals and homes of Pennsylvania on the ground that they are sectarian institutions has been brought into the Dauphin County court. The petition filed in the case contends that payment of appropriations is against the constitution, it being charged that "no appropriations, except for pensions or gratuities for military service, shall be made for charitable, educational or benevolent purposes to any person or community, or to any denominational or sectarian institution, corporation or association."

Philadelphia

Parents Asked to Aid in Health Campaign.—To protect children against the disease infection to which they will be exposed through close contact with one another in the public schools, the state health department has launched a "better health" campaign. A number of helpful suggestions have been explained to the parents, and if these instructions are obeyed, parents will not only be doing the best thing for the interest of their own children, but they also will render a valuable service to the community in general.

Recreation Centers Aid Many to Health.—The city, in its thirty-five or more recreation centers and playgrounds, is spending thousands of dollars to keep not only young men, but also the public, generally fit to defy disease and the ailments that are likely to attack an undeveloped body. The recreation centers are fitted with gymnastic apparatus and have staffs of trained teachers. The grounds are equipped with tennis, handball, basketball and volleyball courts, baseball diamonds, football gridirons and for other games. There are individual lockers and hot and cold showers, and clean, sterilized towels are also supplied. For the children there are gamerooms, with many sorts of games, a reading room, and club meeting rooms.

TENNESSEE

Hospital Items.—Arrangements have been made with hospitals of Memphis to care for discharged soldiers who, owing to the crowded condition of the Marine Hospital, cannot be placed in that institution. The Baptist, General and St. Joseph's hospitals have volunteered their services in caring for white men, and negroes will be cared for at the Wilcox Hospital.—The new Fort Sanders Hospital will be completed by November 1. The hospital will accommodate sixty-five patients, and, when completed, will have cost about \$125,000.

Personal.—In recognition of his efficient work in the treatment of influenza patients of Bemis, during the epidemic last year, Dr. Andrew E. Brown has been awarded a bonus of \$1,000 by the Bemis Brothers.—Dr. Charles B. Crittenden, Nashville, head of the state bureau of rural sanitation has commenced work in Madison County, with headquarters at Jackson. The state and county have appropriated \$10,500 for this work in Madison County, which has been made the administration center for west Tennessee.—Dr. William G. Saunders has been reappointed city physician of Jackson.

WISCONSIN

Personal.—Dr. Asahel W. James, Muscoda, has returned after more than a year of duty with the American Expeditionary Forces in France.—Dr. Louis M. Field has commenced his official duties as city health officer of Beloit, succeeding Dr. William L. Holt, resigned.

CANADA

Hospital News.—To perpetuate the memory of relatives lost in the great war and to meet the shortage of hospital accommodation in Montreal, a group of citizens have decided to associate themselves to build St. Mary's Memorial Hospital. Many Montreal families have expressed themselves as favoring the proposition and have promised to endow beds in memory of lost sons, husbands or fathers. The hospital is to be open to all classes in the community. An appeal for funds is to be made in October by the provisional committee.

Personal.—Dr. H. O. Collins of the Winnipeg General Hospital, Winnipeg, Man., has been elected superintendent of the Iowa University Hospital, Iowa City, succeeding Dr. Willard T. Graham.—Dr. George W. Badgerow, C. M. G., London, England, is visiting in Toronto for a month.—Dr. William B. Hendry, Toronto, who returned with the University of Toronto Base Hospital a short time ago as O. C., has been appointed associate professor of gynecology in the medical department of the university.—Dr. P. Walter H. J. McKown of the Kitchener Hospital at Brighton, England, has returned to Toronto.—Dr. Benjamin P. Watson has returned to Toronto after a visit to Belgium.

Public Health News. Hon. Newton W. Rowell is in charge of the organization of the new federal ministry of public health at Ottawa. The first step in organization consists in the taking over of the various departments dealing with health matters, which have heretofore been scattered over different ministries. Already the department of quarantine has been taken over from the agriculture minister and also immigration and the administration of foods act and the proprietary and patent medicine acts. Dr. Norbert J. Amyot, the deputy minister, is taking up with the provincial departments of health plans for the cooperation between the federal and the various provincial bodies, especially as to the combating of the venereal diseases. A definite announcement will shortly be issued of the policy of the federal department of health. The province of Quebec, within recent years, has made good progress in public health matters. In pure water alone, Quebec probably leads all the provinces. Out 3.8 per cent., 52,879 people, of a population living in

cities, towns and villages of over 500 in population (1,383,729) rely on wells or lake water for their water supply, while 86 per cent. of the users are supplied with water which has undergone treatment in either filtration plants or chlorination. This has eventuated in much decreased typhoid. The adoption of the system of public nurses in baby welfare work is being rapidly extended. The idea is to better establish between health authorities and people the personal contact which is incomparably more effective than any other means of promoting health education.

GENERAL

Hospital Association to Meet.—The American Hospital Association will hold its annual convention at Cincinnati, September 8 to 12.

Bequests and Donations.—The following bequests and donations have recently been announced:

Pennsylvania Hospital, Philadelphia; Church Home for Children, Philadelphia; Philadelphia Orthopedic Hospital and Infirmary for Nervous Diseases, and Philadelphia Children's Hospital, each \$5,000, and Hospital of the Episcopal Church, Philadelphia, \$2,000, by the will of Emily Pratt.

The Dowst Homestead, Waukegan, valued at \$150,000, to be converted to the Fine Dowst Emergency Hospital, in memory of his mother, by the will of Mr. Dowst, Waukegan.

Tuberculosis Conference.—The Mississippi Valley Conference on Tuberculosis will meet in Des Moines, Iowa, September 22 to 24. This conference includes delegates from Ohio, Indiana, Illinois, Iowa, Nebraska, North Dakota, South Dakota, Minnesota, Wisconsin, Michigan and Missouri. Delegates are also expected from Kentucky, Kansas and other states. The Iowa Trudeau Society has already sent an urgent request to each county medical society to name three delegates to the conference. Chief in the themes to be discussed are occupational therapy for the tuberculous, the county survey clinic, the modern health crusade, follow-up care for discharged tuberculous soldiers, and the health officer's part in the tuberculosis movement.

Women Physicians' Conference.—Health, the psychologic aspects of the sex question, and legislative measures as they reflect the present status of sex morality, will be the three divisions of the program intensively to be studied by women physicians at the International Conference of Women Physicians, to open in New York, September 15, and to continue for six weeks. The hostesses for the conference are the social morality committee, the war work council, the national board of the Young Women's Christian Association. Among the women physicians from abroad who have accepted the invitations of the conference are: Betty Agerholm, Copenhagen; Joanne Feilberg, Copenhagen; Phoebe M. Powell-Bigland, Liverpool; Mary Gordon, London; Alice Hartmann, Paris; Anna Montet, Lyon; Yvonne Pouzin, Nantes; Ada Potter, Utrecht; Anna Borrine, Torino; Clelia Lollini, Rome; Dagny Bang, Christiania; Regina Stang, Christiania; Mrs. James C. Johnston, Edinburgh; Gerda Kjellberg-Romanus, Stockholm; Alma Sunquist, Stockholm; Marie Feyler, Lausanne; Frieda Ottiker, Berne; Minna Tobler-Christinger, Zurich; Nathalie Witsch-Malecki, Lausanne; Harriet Jane Parrell, Basel; Marguerite Giboulet, Paris, and Marie Louise Lawaese-Delhay, Antwerp. Doctors from India, South America and Canada are also expected and three from China have accepted. During the war a staff of 145 women physicians was called together under the section on women's work with the social hygiene division of the committee on training camp activities of the War Department and these physicians gave in eleven months and a half, 6,188 lectures to 963,043 women and girls. The demand for the work was so strong, that the social morality committee has continued its efforts so that in March, 121 lectures were given, in April, 597, and in May, 1,111. The chief topic first to be presented for discussion, will be "The Woman Physician and the Health of Women," second, "The Present Social Conditions and Their Effect on Health and Personality," and third, "The Presentation of the Practical Program for Meeting the Needs of Girls in the Light of a Better Understanding of Their Emotional Life."

FOREIGN

Death of Dr. Dominici. The death of Professor Dominici is reported from Paris. Dr. Dominici was very well known for his work on lymphatics and hematosis. His methods of teaching attracted to his classes a large number of students.

Spanish Physicians in the Senate.—At the senatorial elections held recently in Spain the following physicians were elected to that body: Drs. Nicolas Rodriguez, Luis Ortega Morejon, Ricardo Royo Villanova, Rodolfo del Castillo Ruiz and Luis Fatás.

Veneral Diseases in the State Examination.—The Netherlands Society for Repression of Veneral Diseases recently petitioned the government to add the words "skin and venereal diseases" to the list of subjects in which students have to be examined for their degree. The society added that a specialist in venereal diseases should be on the examining board.

Deaths in the Profession Abroad.—Dr. Magnus Gustav Retzius, formerly professor of anatomy at the University of Stockholm, and author of numerous works on anatomy and biology, aged 77.—*The Nederlandsch Tijdschrift* reports the death of Dr. F. Merkel, professor of anatomy at the University of Göttingen, aged 74, and of Dr. E. Gasser, professor of anatomy at the University of Marburg, aged 72. It is an odd coincidence that these three eminent professors of anatomy, all in the seventies, are the only deaths mentioned in the current foreign exchange mail.

The Rotgans Prizes for Cancer Research.—These prizes are open only to research workers in the Netherlands or Netherlands colonies. They are to be awarded from the income of the sum presented to Professor Rotgans of Amsterdam by his friends and pupils on the twenty-fifth anniversary of his professorship. He turned the sum over to the Netherlands Cancer Institute, specifying that the income of this "Rotgans-Fonds" is to be applied in prizes for current research on cancer and allied diseases. The entire sum can be awarded as a prize for any one, irrespective of nationality, who is deemed by the committee in charge to have discovered a sovereign remedy for cancer.

Netherlands Institute for Research on Nutrition.—It is announced that plans for the *Nederlandsch Instituut voor Volksvoeding* are well under way and funds have been secured by donations and state subsidies nearly sufficient for the purpose. It is proposed to found a laboratory along the same lines as the Nutrition Laboratory of the Carnegie Institution in Washington, D. C. Both scientific and practical work will be done, and bulletins published, with popular lectures, all striving to promote and improve food conditions and the dietaries of the Netherlands people. Prof. E. C. van Leersum is mainly responsible for the success of the institution, but it will be managed by a board of experts. Professor van Leersum, it is said, is soon to visit this country on a tour of investigation.

LATIN AMERICA

Portuguese Surgeon Visits Brazil.—Dr. Augusto Monjardino, one of the professors of the School of Medicine of Lisbon and one of the prominent gynecologists of Portugal, is now in Brazil making a tour of the hospitals there. He is accompanied by his brother, Dr. Jorge Monjardino, the well known surgeon.

Medical Congress in Chile.—During the month of September there will be held at Santiago de Chile the Second National Medical Congress. Among the subjects to be discussed appear the following: the law on accidents of labor; popularization of child welfare work; medical work in hospitals; vital statistics; alcoholism, and tuberculosis.

Typhus Fever in Mexico City.—The last report published by the Superior Board of Health of Mexico shows that during the month of April there were reported sixteen cases of typhus fever in Mexico City.—The total number of deaths reported during that month was 1,028, which is considerably below the average mortality of the last twenty-three years.

Typhoid Fever in Uruguay.—A recent report submitted to the National Board of Health by Drs. Justo F. González and Antonio S. Viana shows that typhoid fever has caused an average of 57.4 deaths during the last ten years in Montevideo. The authors recommend the general enforcement of antityphoid vaccination and the compulsory reporting of the disease. The plan submitted by them was approved by the board.

Deaths in the Profession.—Dr. A. Rodríguez Ecay, one of the older members of the profession at Havana, aged 70. He took a prominent part in the organization of the municipal public health service and in the various medical scientific meetings that have been held in Cuba, and was one of the founders of the Sociedad de Estudios Clínicos.—Dr. Manuel S. Guerrero y Ramírez, a leading physician of Manila, member of the Council of Hygiene of the Philippine government, vice president of the Colegio Médico-Farmacéutico and editor in chief of the *Revista Filipina de Medicina y Farmacia*, secretary of the National League for Child Welfare Work and an authority on beriberi in infants. He was born at Manila in 1877, and succumbed to cancer, aged 42. Besides

numerous publications on beriberi and other medical topics, he published under the pseudonym of M. Tralla articles of general literary interest.—R. García Gastañeta, a recent graduate at Lima, who succumbed to bubonic plague contracted at the bedside of a patient.—Dr. Francisco Liongson of Bacolor, Philippines, president of the board of health of the province and at one time governor; now senator from four provinces, aged 50. He obtained his degree from the University of Madrid in 1893.—Dr. J. Antonio Villagrán of Guatemala, a victim to his zeal in combating the epidemic of yellow fever in Guatemala during the last six months, aged 30. He was one of the founders of the society *La Juventud Médica* and editor of its monthly journal. The last issue contains his reports on the epidemic, with editorial comment to the effect that the data prove that Guatemala is not an endemic focus of yellow fever.

MEXICO LETTER

MEXICO CITY, Aug. 24, 1919.

Yellow Fever

To judge from the news, which is not very satisfying, that reaches us from Yucatan, it has not been possible thus far to control completely the epidemic that made its appearance several weeks ago, in that peninsula.

Opium Investigation

The courts of justice are investigating the discovery of a large quantity of opium which has been found in the house in which a well-known chemist has his office. According to newspaper accounts, this opium was intended for non-medical purposes.

Dehydration of Mexican Bananas

Dr. Tomás Peñiczer, the Mexican consul in Philadelphia, suggests in an official communication recently published in the newspapers that the farmers of the so-called *tierra caliente* (the hot belt) of Mexico, especially those in the state of Tabasco, should investigate immediately the methods of drying bananas in order to meet the present scarcity of shipping facilities and be able to continue sending to the United States the large quantities of bananas which are marketed there.

Scientific Contest

Dr. Philippe Gracieux, editor of the *Crónica Médica Mexicana*, has opened a scientific competitive contest under the patronage of the School of Medicine. There will be two prizes, one of 1,000 pesos (\$500), donated by a French industrial corporation, to the physician or medical student, irrespective of nationality, but residing in this country, who shall submit the best article furthering in some way the knowledge of typhus fever. The second prize of 200 pesos (\$100) is donated by the journal itself and will be granted to the medical student who submits the best thesis giving the result of his personal observations or investigations on some therapeutic subject. The judges of the contest will be selected by the dean of the School of Medicine.

Adjournment of the National Academy of Medicine

The National Academy of Medicine has adjourned until October, 1919. Its sessions, which were supposed to end in July, had to be extended in order to decide certain questions it had under consideration. Among these were establishment of the rules that shall govern the contest of the *Universal*, mentioned in a previous letter, in regard to the discovery of the typhus fever germ. The academy decided that the contest should be limited to those physicians licensed to practice in Mexico and that it should close Dec. 31, 1919. The first requirement seems rather rigid since similar contests on the same subject have been open to all investigators, irrespective of nationality, and have not even required the contestants to be physicians, the decision being based only on the merit of the work.

The academy has begun again the publication of its journal, *La Gaceta Médica*, and the first number does credit to this society. The *Gaceta* is managed by Dr. Everardo Landá whose address is Apartado postal No. 517.

Dr. Briso Vasconcelos has been made a member of the academy to fill a vacancy in the section of dermatology and syphilography, his thesis on the modern treatment of neurosyphilis having been accepted.

Personals

Among the well known men whose deaths are reported are Dr. Ignacio Capetillo, a former professor of clinical

obstetrics in the School of Medicine, aged 74 years, and Prof. Adolfo Castañares, director of the School of Chemistry and Pharmacology, aged 39 years.—Dr. A. Cornillon, a prominent member of the French colony who had been in Europe since the beginning of the war, giving his services to France, has returned to this country.—Charges of having violated the constitution have been preferred in congress against Alfonso Cabrera, governor of the state of Puebla. One of the charges concerns the closing of the state college of Puebla apparently because it had become a center of political opposition to the local government.

PARIS LETTER

PARIS, Aug. 7, 1919.

Industrial Service That Mutilated Man Can Render

At a recent meeting of the Academy of Medicine, Drs. Gourdon and Dijonéan endeavored to determine the exact industrial value of mutilated men employed as workmen in a workshop or factory. They reported their conclusions with regard to the exercise of the trade of *ajusteur* (assembler, finisher or fitter), which is one of the most popular on account of the high salaries paid. In order to establish a definite basis for their investigations, Gourdon and Dijonéan set about to ascertain what the conditions were under which a fitter worked in a shop or factory. They studied his standing position, the movements of the upper limbs, what efforts were required in the management of the different tools, and what degree of endurance was required by an ordinary day's work.

Men who have lost only one lower limb, who have suffered the shortening of a limb or paralysis of one of the terminal branches of the sciatic nerve, if they are provided with prosthetic appliances, are adapted for the various kinds of work of a fitter. Those who have lost a forearm or a hand, and those who have suffered, unilaterally, pseudarthrosis of one of the bones of the forearm or ankylosis of the elbow at an obtuse angle, can perform only part of the work of a fitter, since they are able to use only a file, a hammer, carving tools and a scraper.

All other mutilations of an upper limb constitute a contraindication as regards the work of a fitter of any kind, even though requiring the use of very few tools.

The International Council for Scientific Research

At the last two meetings held in London and in Paris by the international conference of the scientific academies of the Entente (THE JOURNAL, Dec. 28, 1918, p. 2167, and Jan. 11, 1919, p. 133), the matter was discussed and it was decided to form a permanent international council to be known as the Conseil international de recherches scientifiques.

The council's committee on organization has recently adopted the article of the constitution and by-laws which establishes Brussels as the seat of the council. Here all the scientific communications that are received will be deposited, and here all gifts and bequests will be kept, after such manner as conforms with the laws of Belgium.

The bibliographic section has proposed that the Conseil de recherches shall absorb the Institut international de bibliographie, and suggests that an Office international de brevets et de documentation technique shall be formed, with its seat at Brussels, to take the place of the German organization which existed before the war and which sought to keep the industries of the world under its control. Four sections of the council have already been organized: astronomy, geodesy, chemistry and bibliography. The sections of medicine and physics are in process of organization.

The Belgian Red Cross

The Red Cross of Belgium will soon have completed its reorganization. At the present time a provisional committee is at work, directed by Dr. Depage, the surgeon who, during the war, was the founder and the chief of the Ocean hospital. New by-laws are to be drawn up and submitted for royal sanction. In accordance with the usual custom, they will be pre-sented for approval to the international committee of the Red Cross in order that the latter, being fully acquainted with the matter, may accredit the new Belgian Red Cross to the other branches of the society, in case such a reaccrediting shall seem necessary.

Personal

At the meeting, July 29, the Academy of Medicine elected Dr. Desgroz, professor of biochemistry at the Paris School

of Medicine, as an active member in the section of physics and chemistry as applied to medicine.

Death of Dr. Reynier

Dr. Paul-Antoine Reynier, who occupied a professorial chair in the Paris School of Medicine and was an honorary hospital surgeon, died recently from pneumonia at his home in Villegondin (department of Loir-et-Cher). He was an active member of the Academy of Medicine and had served in the section of anatomy and physiology since 1904.

MADRID LETTER

MADRID, July 28, 1919.

Present Condition of the Medical Profession in Spain

In Spain the social condition of physicians today is practically that which the medical professions of other countries enjoyed before the organization of associations which improved their status. Every one feels the need of union, every one understands that the present isolation is suicidal, but the mutual lack of confidence and petty jealousies prevent progress.

There are in Spain, a country of 20,000,000 inhabitants, ten schools of medicine and the number of students of medicine exceeds those enrolled in the other subjects (law, pharmacy, science and letters). The eagerness shown by young men to obtain the degree of M.D. is fostered by a curious idea which some medical schools and many professors have of their duties. The former, in order to increase the importance of the towns where they are located and the latter to become popular, pass almost all the pupils they examine. In this way the number of physicians has increased to such a degree that there has been formed what we may call a medical proletariat. All cities and villages are overcrowded with physicians and there are physicians in excess for every occasion when only one is needed. As the supply exceeds the demand by far, the medical service is degraded. As exposed by Dr. Angel Pulido, when he was president of the Medical Society of Madrid, some physicians in the capital of Spain charge 10 *céntimos de peseta* (about 2 cents) a visit or agree to treat patients at the monthly rate of 1 *peseta* (19 cents). I may add that there are over 2,000 physicians at Madrid, a city with 600,000 inhabitants.

The difficulties with which the physicians struggle have been aggravated by the appearance of the wrong kind of leaders who advise violent measures to conquer an evil which requires careful and wise attention. A few years ago the association of municipal physicians was created, but its management was so unfortunate that the government compelled the directors to give an account of the funds in their charge and return to the members over a million of *pesetas* (about \$200,000) then available. The real trouble is that physicians—instead of helping themselves—want somebody else to help them out and place all their hopes in the government.

Payment of Municipal Physicians by the Government

Municipal physicians have always been unanimously in favor of payment by the government. Dr. Cortezo succeeded in having the government issue a decree that thereafter preference would be given by the municipalities to the payment of the salaries of municipal physicians and that the budgets of the city councils would not be approved unless the physicians' salaries were included. This implied a positive improvement since many councils owed to their physicians salaries amounting to several millions of *pesetas*. A number of the agitators were, however, not pleased and have continued their protests, although it is evident that the government cannot undertake the payment of the physicians' salaries at present.

A typical sign of the jealousies and rivalries that prevail in Spain came to light in the memorial presented at the recent medical congress by the School of Medicine of Cáceres which charged in substance that the physicians residing at Madrid did not know the meaning of the phrase "professional fellowship" in their relations with physicians of other towns and that the only standard applied in Spain to judge of a physician's ability was the size of the town in which he practiced.

Autonomy of the Universities

Closely related to the present unrest among the medical profession, the real source of which is the excessive number of physicians graduated from the universities, is the autonomy or self-government granted recently to the universities. These used to be self-governing, and they had in those

a long and often brilliant history, since Salamanca, Alcalá de Henares and others which obtained worldwide reputation in past centuries, were all independent, self-governing universities. The abuse which they made of this power resulted in the taking away of their autonomy. After a time a number of professors asked that autonomy should be granted again to the universities as the only way to give new life to academic teaching and infuse new love for science. A secretary of public instruction, the second one of the three we have had this year, suddenly granted the autonomy desired by the universities and entrusted to them the preparation of their own by-laws and rules. We had then the curious spectacle of a number of professors publishing articles in which they expressed doubts as to the wisdom of the measure and the fear that it might be premature.

Medical Teaching in Spain

There is no question that the number of universities which have medical departments is by far too large, the majority not possessing adequate resources or facilities for demonstrations or experiments. The teaching is so theoretical that if a foreigner who did not know the language attended the courses, he would get as much benefit as if they were classes in theology. The course embraces nominally eight months (from October to May) and lasts seven years. An examination is required for each subject. This examination is held in June and if the student fails he can take it again in September. At the end of the medical course, there is a general examination which, if successful, will secure for the student the degree of Master of Medicine and permit him to practice his profession. The degree of doctor requires another year of study in Madrid, and the secretary of public instruction may or not at his discretion require the student to prepare a thesis to be judged by the medical staff.

The examinations used to be held before three professors, but recently this was changed and only one professor is now in charge of the examination. This was really the beginning of the increase in the number of students, since after the change the number of those failing to pass the examinations decreased considerably, and some professors boast that they have never had one of their pupils fail.

In Spanish universities there are two kinds of teaching: the official, in which the student attends the classes of the university professors and the optional or "free," in which the student studies wherever he pleases and presents himself in June or September for examination.

Apapros of the autonomy recently granted to the universities, Cajal has given out an interview regretting the constant changes in the department of public instruction, which with each new secretary result in corresponding educational changes. We have had in the last three years three general elections and not less than ten different cabinets. He suggests, therefore, that all secretaries should be kept in power at least six years, so that they may devote the first two years to comply with the demands of their relatives and friends; the next two they will study the work of their departments and finally in the last two years they will be able to achieve something.

Death of Dr. Tolosa Latour

Very suddenly, when he seemed in the prime of health and on the very day before the Royal Academy of Medicine was going to elect him a senator, there occurred the death of Dr. M. Tolosa Latour, one of the most prominent figures of Spanish medicine. Dr. Tolosa Latour was a distinguished writer who did much to popularize science, a worshiper of art and had a heart of gold. He had devoted his whole life to children, had become a famous specialist in pediatrics, and was instrumental in securing the passage of the law for child welfare. He founded and supported until his death the seashore sanatorium at Chipiona, the first one of its kind in Spain.

Death of Dr. Gómez Ocaña

In my previous letter, I referred to the address delivered by the chairman of the First National Congress of Medicine in Spain. In my present letter, I have to communicate the news of his death. Dr. J. Gómez Ocaña became professor of physiology at the School of Medicine of Madrid after holding the same place at Cádiz. His experimental studies on the thyroid gland made a name for him. He was an excellent teacher and his studies on Cervantes and his times attracted much attention. He was a member of the academy, a life senator and when he referred to himself at the closing of the medical congress said "I am not sure whether I have taught physiology to my students. I know, however, that I have taught them to be good men and to love Spain."

LIMA LETTER

LIMA, July 24, 1919.

Yellow Fever at Piura

Owing to the frequent intercourse between the department of Piura and the region surrounding Guayaquil, Ecuador, a mild epidemic of yellow fever has occurred in this northern province of Peru. A commission consisting of Major Henry Hanson of the U. S. Army Medical Corps, who is now on duty in this country, an engineer, and two assisting physicians, has been sent from Lima and has already begun its work. According to the available information there have been about thirty cases of yellow fever with a total of ten deaths. The port of Payta, the first one on the Peruvian coast, has also been affected by the epidemic and the necessary measures have been taken to prevent the spread of the disease and to make all ships comply with the provisions of the International Sanitary Convention of Washington.

Malaria in Lima

Malaria, which is endemic all along the Peruvian coast, has shown a very marked increase in the capital of the republic and in the adjoining valley. The mortality from this disease reached last year a total of 266 as compared with 112 reported the year before. Dr. Hanson had been engaged to eradicate this disease, but he had to be sent to control the yellow fever outbreak.

Commission on Rural Sanitation

The ravages of malaria have induced the society of civil engineers to create a commission on sanitation which, in cooperation with other agencies, will devote its efforts to the improvement of rural sanitation in this country. The commission has published for distribution an interesting pamphlet on this subject. Dr. C. E. Paz Soldán has been chosen president. One of its members is S. Gutiérrez, an engineer who now occupies a seat in the cabinet, being the head of the department of the interior and sanitation. It is to be hoped that this commission will meet with success.

Symposium on Influenza

The National Academy of Medicine of Lima has devoted two sessions to a discussion of various reports bearing on the pandemic of influenza in this city. According to the papers presented, the influenza here did not show any difference in its clinical, anatomic, pathologic and bacteriologic characteristics from those it presented in other parts of the world. It is worth noting, however, that in Lima the influenza did not cause such an excessive mortality as at other points. Dr. A. Corvetto, a member of the academy, presented an interesting paper showing with abundant evidence that tuberculosis was seldom influenced by influenza.

Progress in the Study of Odontology

As the result of the efforts of Dr. W. S. Salazar, the director of the dental school, a new dental clinic was opened at Lima last month which will be used for the teaching of odontology. The physicians in this city view with approval this new undertaking.

New Trustees for the National Academy of Medicine

The Academia Nacional de Medicina has appointed its new board of officers for the year 1919-1920 as follows: president, E. Pardo Figueroa; vice president, Dr. E. Odriozola; secretaries, Drs. C. E. Paz Soldán and A. Corvetto; treasurer, Dr. E. Bello; members, Drs. J. Dengri and W. S. Salazar.

Marriages

ALLEN CALLENDER SUTTON, Capt., U. S. Army, Baltimore, to Miss Clara A. Wagner, at Roland Park, Baltimore, August 16.

JOHN SEGWICK DORSEY, Mount Rainier, Md., to Miss Margaret R. Neave of Dresden, Ohio, at Annapolis, Md., August 14.

SAMUEL HENRY KAGAN, Capt., R. A. M. C., Augusta, Me., and Boston, to Mrs. Violet Barnes of London, England, June 21.

BERNARD PIERRE WIDMANN to Miss Mary Eileen Maher, both of Philadelphia, August 27.

GEORGE JOSEPH HANCE, Troy, Ohio, to Miss Mary Johnson of Cincinnati, September 1.

LYNDON DENNY HARRIS to Miss [Name obscured], both of Chicago, recently.

Deaths

Joseph Zeisler ★ Chicago; died suddenly in the Grand Hotel, Mackinac Island, Mich., August 31, from angina pectoris; aged 60. Dr. Zeisler was born in Bielitz, Austrian Silesia; was graduated in medicine from the University of Vienna in 1882; and after serving as an intern in the Vienna General Hospital for two years, came to America and settled in Chicago in 1884. In 1888 he began his teaching career as professor of skin and venereal disease in the Post-Graduate Medical School; a year later he became professor of dermatology in the Northwestern University, Woman's Medical School, Chicago, and in the same year was made professor of skin and venereal diseases in the Northwestern University Medical School, holding the latter position as professor emeritus at the time of his death. He was chairman of the Section of Dermatology of the American Medical Association in 1912-1913, president of the Chicago Dermatological Association in 1904 and 1914, and president of the American Dermatological Association in 1903-1904; he was also chief dermatologist to Mercy, Wesley and Michael Reese hospitals, and to the South Side Free Dispensary. Dr. Zeisler in addition to his professional attainments was a man of charming personality, a musician of high ability, and took a great interest in arts and letters.

Lucien Guy Heneberger ★ Med. Dir. (Capt.), M. C., U. S. Navy (retired), Washington, D. C., and Newport, R. I.; University of Virginia, Charlottesville, 1872; aged 67; who entered the Navy in 1874; was made surgeon in 1890 and medical director in 1908; was one of the officers of the *U. S. S. Maine* when she was sunk in the harbor of Havana in 1898; physician at the White House during President Arthur's administration; and who was retired, Oct. 20, 1913, on attaining the age of 62 years; died in the U. S. Naval Hospital, Washington, August 3.

Edward Larnedo McGhee ★ Hammond and New Orleans, La.; Tulane University, New Orleans, 1874; aged 67; once president of the Mississippi State Medical Association; professor of physiology, hygiene and pathology in the New Orleans College of Dentistry; president of the Louisiana Anti-Tuberculosis League; organizer and superintendent of the Hammond Sanatorium for the Treatment of Tuberculosis; died at his home in Hammond, August 13.

Jesse Williamson, Philadelphia; Jefferson Medical College, 1873; aged 66; a member of the Delaware State Medical Society; at one time a resident of Colorado Springs, Colo.; visiting physician to St. Francis' Hospital, Colorado Springs, and consulting surgeon to the Union Pacific and Denver and Rio Grande systems; died in Bay Head, N. Y., August 17, from angina pectoris.

John Alfred B. Adcock, Warrensburg, Mo.; Eclectic Medical Institute, Cincinnati, 1877; University Medical College, Kansas City, Mo., 1901; aged 68; a member of the Missouri State Medical Association; for many years a member of the state board of health; secretary of the board in 1905 under the administration of Governor Major; died at his home, August 20, from cerebral hemorrhage.

George S. Williams ★ Muskegon, Mich.; Rush Medical College, 1883; aged 63; in 1912 president of the Muskegon-Ocean County Medical Society; a member of the staff of Hackley Hospital, Muskegon; division surgeon of the Grand Rapids and Indiana Railroad; died at his home, August 15, from uremia.

William I. Langfitt, Pittsburgh; Rush Medical College, 1867, aged 81; said to have been the oldest practitioner of Allegheny County; one of the organizers, secretary and director of St. John's General Hospital; for more than seventeen years a member of the Allegheny City school board; died at his home, August 27.

John Vilas Wright ★ Dallas, Texas; University of Texas, Galveston, 1911; aged 33; a specialist in tuberculosis; and for seventeen months medical director of Woodlawn Tuberculosis Sanatorium, Dallas; died in that institution, April 28, following an operation for appendicitis.

William H. Hawkins, Greenville, Tenn.; Louisville (Ky.) Medical College, 1890; aged 58; a member of the Tennessee State Medical Association and a specialist in pediatrics; local surgeon for the Southern Railway system; died at his home, August 18, from cerebral hemorrhage.

John Maynard Emery, Des Moines, Iowa; University of Michigan, Ann Arbor, 1876; aged 62; vice president of the Reinsurance Life Company of America, and a well known consulting actuary; died in Helena, Mont., about August 20, from cerebral hemorrhage.

Charles von Schroeder, Maquoketa, Iowa; Rush Medical College, 1882; aged 60; who soon after his graduation entered the First National Bank of Maquoketa, of which he eventually became president; died at his home, August 18.

Nelson K. McCormick, Normal, Ill.; Northwestern University Medical School, Chicago, 1886; aged 57; president of the board of directors of Brokaw Hospital, Bloomington, Ill.; died in Petoskey, Mich., July 26, from nephritis.

David Mott Robertson, Spout Spring, Va.; New York University, New York City; formerly representative in the state legislature, and treasurer of Appomattox County; died at his home, August 17, from heart disease.

Harry Isaac Newcomet ★ Reading, Pa.; University of Pennsylvania, Philadelphia, 1912; aged 32; who was honorably discharged as lieutenant, M. C., U. S. Army, Dec. 9, 1918; died at his home, about August 10.

Hiram Heaton Swallow, Topeka, Kan.; Starling Medical College, Columbus, Ohio, 1884; aged 63; for twenty years in charge of Merrill Springs Sanitarium, Carbondale, Kan.; died at his home, August 16.

Salathiel A. Hitchcock, Elida, Ohio; Cincinnati College of Medicine and Surgery, 1870; aged 76; a veteran of the Civil War; died at the Lima (Ohio) City Hospital, August 18, from intestinal obstruction.

Charles Toomer Parrish, Portsmouth, Va.; College of Physicians and Surgeons in the City of New York, 1890; aged 52; a member of the Medical Society of Virginia; died at his home, August 6.

George W. Morehouse, Delaware, Ohio; Columbus (Ohio) Medical College, 1880; aged 61; a member of the Ohio State Medical Association; died at his home, August 13, from cerebral hemorrhage.

William Bissell, Lakeville, Conn.; Yale University, New Haven, Conn., 1856; aged 89; a member of the Connecticut State Medical Society; died at his home, July 2, from cerebral hemorrhage.

Paul Hamilton Markley, Camden, N. J.; University of Pennsylvania, Philadelphia, 1882; aged 59; a member of the Medical Society of New Jersey; died at his home, August 28.

William Lee Dalby, Bridgetown, Va.; Medical College of Virginia, 1891; aged 49; a member of the Medical Society of Virginia; died at his home, August 14, from nephritis.

Theodore H. Patterson, Seattle; University of Wooster, Cleveland, 1865; surgeon of the 187th Ohio Volunteer Infantry during the Civil War; died in Seattle, about August 24.

George Walter Nevils ★ Rowesville, S. C.; Medical College of the State of South Carolina, Charleston, 1890; aged 49; died in the Maryland University Hospital, August 5.

William Chatfield Burke, Wykoff, Minn.; St. Louis University, 1915; aged 30; was instantly killed, near Canton, Minn., August 17, by the overturning of his automobile.

Frederick J. Schouten, Holland, Mich. (license, years of practice, Michigan, 1900); aged 76; a practitioner and druggist for forty years; died at his home, August 20.

Frederick J. Lindenschmidt, Milwaukee; Northwestern University Medical School, Chicago, 1883; aged 59; died in his office, August 18, from cerebral hemorrhage.

Lemuel Edwin Willis ★ Newport, Ark.; Missouri Medical College, St. Louis, 1886; aged 57; died in a sanatorium in St. Louis, August 16, from cerebral hemorrhage.

Fletcher Alberto Smith ★ Corinth, N. Y.; Dartmouth Medical School, Hanover, N. H., 1888; aged 62; died at his home, June 27, from cirrhosis of the liver.

William Case Williams, Denver; Eclectic Medical Institute, Cincinnati, 1873; aged 71; died at his home, June 22, from cerebral hemorrhage.

Joseph Van Meter Champion ★ Mansfield, Ill.; Rush Medical College, 1885; aged 62; died at his home, August 7, from valvular heart disease.

Lewis Clark Crowell, Syracuse, N. Y.; Cleveland University of Medicine and Surgery, 1872; aged 72; died at his home, August 2.

James E. Ryan, Redwood, N. Y.; Chicago Homeopathic Medical College, 1880; aged 59; died at his home, July 7.

Samuel L. Rea, Oxford, Pa.; University of Pennsylvania, Philadelphia, 1871; aged 76; died at his home, August 17.

Correspondence

"PROTEOGENS"

To the Editor:—Allow us to direct your attention to several misstatements which appear in the letter signed "Allen W. Freeman, M.D., Commissioner of Health, State of Ohio," published in THE JOURNAL of the AMERICAN MEDICAL ASSOCIATION for July 26.

1. Salesmen of this company have *not* been exhibiting a "letter purporting to show that this department has endorsed their products in the treatment of venereal diseases," as stated by Dr. Freeman.

2. The author of the letter has *not* "made numerous efforts to recall the letter, but the Merrell people profess an inability to control its use," as stated by Dr. Freeman.

A physician employed in one of the clinics used our Proteogens Nos. 10 and 11 extensively and is still using them to a large extent in his private practice. He is a man of standing in the community in which he practices and is also a professor in one of the leading medical colleges in the state.

The letter in question cites the case of a man who had been under treatment for three years with 606, 914 and most of the other treatments in general use, and on August 31, a year ago, still gave a Wassermann test plus 4. He was given Proteogen No. 10, and by the middle of December the Wassermann was negative and the man was discharged as cured.

While this letter was written on the stationery of the Bureau of Venereal Diseases of the Department of Health, State of Ohio, it was written in the first person, and made no pretension in any way to being official nor was any such pretense made or authorized by the Merrell Company.

The author of the letter has *not* made "numerous efforts to recall the letter," nor has the Merrell Company "professed an inability to control its use."

The physician did ask that the letter be returned to him, and his request was complied with promptly.

[Then follows the full text of the letter in question. As its contents have no bearing on the question under discussion, it is omitted.—Ed.]

In over ninety-one years of honorable service as manufacturers of medicinal preparations, the Wm. S. Merrell Company has never endeavored to advance its interests through misrepresentation.

THE WM. S. MERRELL COMPANY,
CHAS. G. MERRELL, Pres.

[The letter above was submitted to Dr. Allen W. Freeman, Commissioner of Health of the State of Ohio. Dr. Freeman's comments appear below.—Ed.]

To the Editor:—The plain issue of veracity raised in the communication of the Merrell Company must be settled on the evidence, which is unfortunately too voluminous to be published in full in THE JOURNAL. Copies of the correspondence in the case have been furnished the editor, and the originals are on file in the office of the state department of health in Columbus.

1. Whether or not the photographic reproduction of a letter written on the letter head of this department, and the distribution of copies to salesmen for display to physicians, was a conscious effort on the part of the firm in question to create the impression that the letter was an official one is perhaps a matter of inference. That it did create such an impression is evidenced by the letters of inquiry received from physicians who saw it.

2. The statement that the Merrell Company refused to return the letter is perhaps erroneous. They did apparently return the original letter but not the *photographic copies* which had been distributed to their salesmen. On May 22 the firm wrote as follows:

"A number of physicians who are in cooperation with both state and national bureaus of venereal diseases have been using our Proteogens with marked success and there are doubtless many letters tried by our salesmen—reports from some of these physicians."

This was interpreted to mean that the firm had no method of knowing what letters were carried by their salesmen and was not responsible for them. Whether or not this interpretation is correct is again, perhaps, a matter of opinion.

The purpose of the original communication was to make plain to those of the profession who have already seen or might subsequently see the letter referred to that the communication was the expression of an individual and not of the Department.

A. W. FREEMAN, Commissioner.

"ABDOMINAL SURGERY UNDER LOCAL ANESTHESIA"

To the Editor:—I was very much interested in the article of Dr. Robert Emmett Farr on "Abdominal Surgery under Local Anesthesia" (THE JOURNAL, Aug. 9, 1919, p. 391). I have no criticisms to make of the surgical aspects of the article, but beg leave to criticize the mechanical end. Why is it necessary to have the complicated mechanical devices portrayed in the photographs when the same results can be obtained by the simple hydraulic pump here portrayed? The only really necessary equipment is an arsenophan apparatus, a cork plunger, and some sort of weight above this,

either a one or two pound metal weight, or a small bottle, say an ounce bottle filled with mercury or with lead shot. What could be simpler, or what could be more beautifully efficient?

Injector for use in local anesthesia.

LUCIUS F. HERZ, M.D., New York.

GERMANY AND IMMUNOLOGY

To the Editor:—A current article by Colonel Vedder on the Wassermann reaction in the *Journal of Immunology* (4:141 [May] 1919) fires a train of thought already laid. Colonel Vedder suggests that the term "Wassermann reaction" be abandoned in favor of "Bordet-Gengou reaction." Partisan as I am of the Belgian school, I regret that I cannot see the force of the argument assigned by Colonel Vedder. He states correctly that, whereas Wassermann's original idea was that his reaction in syphilis was to be regarded as a reaction between a specific antigen (extract of fetal syphilitic liver) and its corresponding antibody, it has since been realized to be nonspecific in respect to the antigen employed. As the reaction of Bordet and Gengou is strictly specific in both respects, Wassermann would seem entitled to credit for developing a novel type of nonspecific fixation reaction of great practical utility.

There are, however, substantial evidences of German usurpation in immunology which it would now be well to destroy not simply for emotional reasons, or reasons of honesty, but in the interest of scientific truth. The entire Ehrlich hypothesis, with its misleading nomenclature, has long been an inhibition to independent scientific thought. With the exception of the earlier work in toxin and antitoxin, the only heuristic value of Ehrlich's theory has been in stimulating Bordet to further fundamental discoveries. Since there are few workers who now believe in more than fragments of the Ehrlich hypothesis, it would seem an advisable moment to abandon most of the Ehrlich terminology. There are, for example, few writers in this field who have had any convictions about the use of the words "alexin" and "sensitizer" in preference to the German terms "complement" and "amboceptor," which seem inextricably fastened on our

scientific literature. Although the word "complement" is not in itself particularly committing, it is less completely explanatory of what we believe to be the ferment-like activity of the substance normally present in fresh serum on which the ultimate destruction of bacteria depends. On the ground of priority and accuracy, the term "alexin," originated by Buchner and functionally defined by Bordet, should take precedence over Ehrlich's "complement." The word "amboceptor" cannot be defended except by the blind adherents of Ehrlich's fantastic theory. Its adoption into common parlance is due undoubtedly to the fact that most workers who apply this term have been engaged in a purely practical application of the facts of immunology rather than possessed of first-hand information on the mechanism of the reactions themselves. A careful inspection of the literature should convince one that the immune substance in serum has never been demonstrated to be capable of combining with the alexin without previous union with the antigen as implied in the term "amboceptor" (compare Bordet and Gay: *Studies in Immunity*, p. 363).

Another evidence of the extent to which German science has imposed on us is the frequent incorrect use of the reaction designated as deviation of complement (Neisser-Wechsberg phenomenon) when the fixation reaction of Bordet and Gengou is in reality intended. As an example, one may instance a recent editorial in *THE JOURNAL* ("The Complement Deviation Reaction in Tuberculosis," Aug. 9, 1919, p. 424). It seems scarcely necessary to reiterate that the two reactions are quite different in detail, significance and applicability, and the choice of the German and incorrect reaction for the Franco-Belgian phenomenon is more than the result of chance.

It will probably be years before these incorrect hypotheses and terms riveted on our literature by successful German propaganda are eliminated. Now, however, would seem the suitable moment to begin the process of freeing ourselves from some of these fetters.

FREDERICK P. GAY, M.D., Berkeley, Calif.

THE CAUSE OF EDEMA

To the Editor:—The editorial comment on "The Cause of War Edema" (*THE JOURNAL*, July 26, 1919, p. 274) refers to an article (Kohman: War Dropsy, *Proc. Soc. Exper. Biol. & Med.*, 16:121 [April 16] 1919) in which the views concerning the role of protein in the causation and relief of "war edema" are similar to those expressed by me on various occasions, concerning the development of edema in certain types of renal disease. It may be of interest to refer to the two papers published by me on the subject:

1. The Nature and Treatment of Chronic Parenchymatous Nephritis, *THE JOURNAL*, Aug. 11, 1917, pp. 444-447.
2. Concerning the Causation of Edema in Chronic Parenchymatous Nephritis, *Am. J. M. Sc.*, 151:658 (Nov.) 1917.

My object in writing is not merely to call attention to these publications but to add corroborative evidence on the probable cause of the condition, which has been little understood in the past.

ALBERT A. EPSTEIN, M.D., New York.

COMMENT. Miss Kohman, whose work was commented on in our editorial, observed the appearance of an unusual edema in animals that were kept on a ration in which carrots supplied the protein. Obviously the nitrogenous intake was at a rather low plane. When protein was added from other sources the edema was averted.

Edema is known to occur in man in cases of chronic parenchymatous nephritis. Epstein's hypothesis for its production (*Am. J. M. Sc.*, 151:658 [Nov.] 1917) is briefly as follows: In this disease a hydramia undeniably occurs; and in the parenchymatous type the amount of protein in the blood is markedly diminished, presumably because of the loss of protein in the urine. The decrease seems to be proportional to the duration and intensity of the disease. We may assume on the basis of Starling's views that the loss of protein incurred by the blood serum through the continuous albuminuria causes a decrease in the osmotic pressure of the blood, thereby favoring the absorption or imbibition and retention of fluid by the tissues.

According to Epstein, therefore, the problem in the treatment of edema in chronic parenchymatous nephritis is to relieve the condition and prevent its occurrence. Mere removal of the effusion fluid is not sufficient. A normal condition of the blood must be restored and nutrition must be improved. Massive transfusion has a partial usefulness, but adequate dietary measures are most potent. Epstein's plan consists in the administration of large quantities of properly selected protein with a minimum of carbohydrates and the exclusion of fats. He restricts the carbohydrates "to promote a maximum assimilation of protein and to exclude the greater production and retention of water which is incidental to the metabolism of carbohydrates."

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

BENZYL BENZOATE AND AROMATIC ELIXIR OF ERIDIOTYON

To the Editor:—Will you be kind enough to have some one look up the place or places where I can obtain benzyl benzoate? I have been reading the articles on the use of that but cannot find any drug firm that makes it.

JESSE L. RUSSELL, M.D., Adairville, Ky.

To the Editor:—Kindly advise me where (1) benzyl benzoate and (2) elixir of eriodictyon may be obtained.

T. G. H. DRAKE, M.D., Caron, Sask.

ANSWER.—1. *THE JOURNAL* has received numerous inquiries relative to benzyl benzoate, a substance which is discussed in two articles in *THE JOURNAL*, Aug. 23, 1919, by Dr. David I. Macht, "A Therapeutic Study, Pharmacologic and Clinical, of Benzyl Benzoate," and by Dr. Jennings C. Litzenberg, "The Use of Benzyl Benzoate in Dysmenorrhea." The only preparation thus far accepted by the Council on Pharmacy and Chemistry for inclusion in New and Nonofficial Remedies is that manufactured by Hynson, Westcott & Dunning, Baltimore (see New and Nonofficial Remedies, 1919, p. 53). The drug may be obtained directly through this company or indirectly through wholesale pharmaceutical companies.

2. Eriodictyon—yerba santa leaves—is official in the United States Pharmacopoeia. The elixir is included in the National Formulary; it contains fluidextract of eriodictyon, 6 per cent.; compound elixir of taraxacum, about 44 per cent., and syrup (see Epitome of the Pharmacopoeia of the United States and the National Formulary, p. 83).

NICKEL DERMATITIS

To the Editor:—Can you recommend prophylactic or active treatment for the dermatitis caused by working in nickel plating?

A. L. C.

ANSWER.—An eczematous inflammation of the skin has been described as occurring among workers in nickel plating establishments. The disease affects the hands first and may spread over the arms, occasionally even involving the skin of the entire body. The skin becomes inflamed, and vesicles appear on the affected part. The nickel sulphate used in electrolytic baths is believed to be responsible for the eruption. The application to the skin of cream or petrolatum is recommended, both as a prophylactic and as a remedial agent. Careful cleanliness and attention given the skin is considered to be by far the most reliable protection against the disease.

PROTEOGENS

To the Editor:—I have just returned to my practice after two years and more of absence in the service. I find myself unacquainted with many new theories and drugs. Just at present I am being flooded with many reprints on new drugs, among which numbers are samples and literature that sounds good referring to Proteogen and more particularly to that of the William S. Merrell Company. What is the standing of this product with the Council?

S. E. R. Rutland, Vt.

ANSWER.—There have probably been no epoch-making advances in medicine during the last two years. As to proteogen: this was discussed in the Council report published in *THE JOURNAL*, July 12, p. 128.

- WYOMING: Cheyenne, Oct. 6-8. Sec., Dr. J. D. Shingle, Cheyenne.

Georgia June Examination

Dr. C. T. Nolan, secretary of the Georgia State Board of Medical Examiners, reports the written examination held at Atlanta and Augusta, June 5-6, 1919. The examination covered 10 subjects and included 100 questions. An average of 80 per cent. was required to pass. Of the 25 candidates examined, 21 passed and 4 failed. The following colleges were represented:

College	PASSED	Year Grad.	Per Cent.

Book Notices

THE AFTER TREATMENT OF WOUNDS AND INJURIES. By R. C. Flindie, M.S., F.R.A.C.S., Brevet-Major R.A.M.C., Special Military Surgical Hospital, Shepherd's Bush. Cloth, Price, \$4 net. Pp. 323, with 144 illustrations. Philadelphia: P. Blakiston's Son & Co., 1919.

There has always been a strong tendency to lay stress on the problems of diagnosis and immediate treatment of the sick and injured, while few authors have ever taken the trouble to follow the treatment of patients with disability through to the point at which the maximum degree of usefulness of the body has been restored. There has been a marked change in our attitude regarding these matters in the past few years, inaugurated by the increasing demands of the rapidly multiplying industrial compensation laws, and brought to a sharp focus by the tremendous problems in physical reconstruction or restitution precipitated by the war. Never before have governments evinced such a definite sense of responsibility to their disabled soldiers as to undertake to restore them to a condition as sound physically as may be before turning them back to civil life on their own responsibility. One result of this has been the concentration of groups of medical officers on the problems of after-treatment under conditions that permit a thorough study of an almost endless variety of pathologic conditions due to trauma. "The After Treatment of Wounds and Injuries" is one of the products of this enlightened policy, and in excellence of plan, scope of material and clearness of exposition it sets a standard for books in this field. The book is a fine sample of exposition by example; the author states the general principles underlying the treatment of certain conditions and follows this by the description of cases in which the treatment described was carried out, in this way making his point plain without becoming verbose.

The keynote of the book is found in the opening sentence: "The ultimate aim of military surgery is to restore the functional utility of the damaged part of the body." With this as the ideal, the author strives to impart that knowledge of pathology and clear appreciation of mechanics which are necessary for the realization of the ideal. The first chapter is devoted to a statement of the principles of reparative surgery. In the second chapter we find a discussion of the treatment of chronic osteomyelitis. The third and fourth chapters deal with the question of malunion of fractures, delayed union and nonunion; the following two chapters are devoted to the reparative surgery of joints; following this, in the order named, are chapters devoted to injuries of the nerves; pathology and diagnosis; surgical treatment of nerve injuries; injuries of the muscles, tendons and skin; functional disabilities; amputations; repair in the upper limb, taking up here the various conditions which may be encountered, such as flail elbow, malunion of the radius or stiffness of the joints of the hand, and showing the application of the principles previously outlined to the management of each condition; injuries of nerves of the upper limb; repair in the lower limb; injuries of nerves of the lower limb; injuries of the spine; splints and surgical appliances; plaster-of-Paris technique, and physiotherapy.

This book is a distinct addition to the literature of reparative surgery and will doubtless be of great value to all who are interested in that work.

COLLOID IN BIOLOGY AND MEDICINE. By Prof. H. Reichenow. Authorized Translation from the Second German Edition, with Notes and Emendations, by Jesse G. M. Billorey, A.B., M.D., Assistant Clinical Professor of Medicine, Fordham University. Cloth, Price, \$5 net. Pp. 464, with 54 illustrations. New York: D. Van Nostrand Company, 1919.

This is a lucid account of colloidal chemistry and its application in medical biology. The author reviews the fundamentals of colloids, the physical phenomena peculiar to this field, and the methods of colloidal research. The biocolloid carbohydrates, proteins, other food products and condiments, enzymes, and immunity reactions are considered especially with regard to the colloidal properties manifested, and the bearing of these on vital and on *in vitro* activities. That portion of the text dealing with the organism as a colloid

system presents the colloid reactions concerned with the distribution of water in normal and diseased tissues. Fischer's theory of edema is discussed fully. There follows a similar discussion of salt distribution, assimilation and dissimulation—processes involving the conversion of crystalloid foodstuff into colloids which may be retained for use. Growth, the formation of layered structures, ossification, and certain pathologic changes are given a colloidal chemical basis. The colloidal chemistry of cells, the movement of organisms and muscle contraction, blood, respiration, circulation, absorption, secretion and excretion are fully discussed, with certain reference also to diseased conditions. The final chapters deal chiefly with the action of foreign chemical substances and organisms, and microscopic technique, both rather broadly. This discussion of colloids in numerous phases of medical biology is especially valuable as a reference to investigators in this or related fields, but is also a pleasing stimulus to the broadly trained, aggressive physician.

AN OUTLINE OF GENITO-URINARY SURGERY. By George Gilbert Smith, M.D., F.A.C.S., Genito-Urinary Surgeon to Outpatients, Massachusetts General Hospital. Authority to publish Granted by the Surgeon-General, U. S. Army. Illustrations by H. F. Atken. Cloth. Price, \$2.75 net. Pp. 301, with 71 illustrations. Philadelphia: W. B. Saunders Company, 1919.

It is rather disappointing to note that neither in content nor in form of expression has the author succeeded in reaching his ambition as expressed in the preface: "The following pages are an attempt to simplify the rather complex subject of genito-urinary disease."

Accuracy of definition and clarity of description are lacking throughout. A few quotations: "In bladders distorted . . . the ureters may be impossible to find" (page 39). "Gonorrhea is at first a disease of the wall of the urethra" (page 77). Mucosa is evidently meant. "A band of scar tissue in the urethral mucosa and submucosa extending around the urethra is a stricture" (page 95). Stricture is not a band but a condition of narrowing of the potential urethral lumen by persistent pathologic changes. Scar tissue in the urethral wall running in a longitudinal direction may also diminish the caliber of the canal. "The resilient or gristly stricture may resist all attempts at dilatation" (page 98). A stricture may be resilient because of the presence of a great number of elastic fibers in the scar tissue. Such a stricture is easily dilated, but very promptly contracts after the removal of the instrument used in dilatation. "A collection of watery fluid is a hydrocele; of spermatic fluid a spermatocele; of blood a hematocele" (page 163). "Practically never do we find infection of the bladder without underlying cause" (page 190). "The escaped urine infiltrates the alveolar tissue of the pelvis and later forms an abscess" (page 214).

In his diagnostic and therapeutic suggestions, the author will undoubtedly encounter opposition. The recommendation of putting a female patient in the knee-chest position for urethroscopy will not be favorably received by most of the interested specialists. This posture is repulsive to most women and disadvantageous to the examiner. The instillation into the urethra of a 4 per cent. cocaine solution before cystoscopy, as advised by the author, is a risky procedure. The urethra, especially if eroded, may absorb the cocaine so rapidly that severe and even fatal intoxication may result. In the discussion of labo due to clancroid, the extirpation of the diseased glandular mass is not mentioned at all. The plunging of the prepuce with gauze during acute gonorrhea will certainly not receive the approval of most urologists. The description of the diagnostic value of bougie à boulie is contrary to the essentials of its use. The optimism of the author in designating a perineal urethrotomy for stricture as a simple enough operation, if a guide can be passed through the urethra previous to operation, will not be shared by experienced operators. In the discussion of hypertrophy of the prostate in men of advanced years, the now generally accepted Zuckerkandl-Fanlder theory is not even mentioned. It is hard to understand how the author succeeds in making the diagnosis of residual urine by rectal palpation and suprapubic percussion. The so-called Army operation is the only

one described in the chapter on varicocele, a method which many have long since discarded because of the frequency of recurrences and the failure to care properly for the open inguinal canal.

Medicolegal

Husband Held Liable for Services Rendered to Wife

(Richard v. Miller (Colo.), 179 Pac. R. 157)

The Supreme Court of Colorado, in affirming a judgment for \$200 in favor of plaintiff Miller, a physician, says that this was an action brought by him against defendant Reahard to recover for medical and surgical services rendered to the latter's wife. The plaintiff, for his right to recover, relied on the common law liability of the defendant, as a husband, for necessities furnished to the wife. The defendant sought to defeat recovery on the ground that, as he claimed, his wife had left him without cause about six months prior to the time the services in question were rendered, and continued to live separate and apart from him up to the time of her death, which occurred shortly after the services, including a surgical operation, were rendered. There was no evidence that the defendant had a home prepared and ready for his wife at any other place than that where she was staying at and before the time the plaintiff's services were sought and engaged. She was then staying at a rooming house. The defendant frequently visited her, and stayed at the rooming house many nights, and during a part of the time remained there every night. It was testified that immediately after his wife died the defendant requested that her earrings be taken off. The evidence also showed that he visited the hospital where his wife was receiving medical and surgical treatment. He held himself out to the plaintiff, and to others, as the husband of the patient. The plaintiff testified that, after her death, in a conversation relating to his compensation, the defendant said "he would pay the bill." These and other circumstances justified the trial court in finding the issues for the plaintiff, and supported the conclusion that there had been no separation between the defendant and his wife. On the whole evidence the supreme court cannot say that the trial court was not warranted in resolving all material issues in favor of the plaintiff. It is of the opinion that there was sufficient evidence to support the findings and judgment.

Diagnosing and Treating Pregnancy as Kidney Trouble

(Stevens v. Yates (Ky.), 208 S. W. R. 820)

The Court of Appeals of Kentucky reverses a judgment that dismissed the plaintiff's petition after a verdict for the defendant had been directed, and orders a new trial, in this action against a woman physician for alleged malpractice in diagnosing and treating a case of pregnancy as one of kidney trouble. The court says that the plaintiff, a married woman 42 years old, in February went to the defendant for proper treatment. This, of course, required as a prerequisite a proper diagnosis of the plaintiff's affliction. The symptoms which she related to the defendant were that she was suffering with shortness of breath, with pains in her back and stomach, and perhaps some others. The defendant made no physical examination, but stood behind the plaintiff while she was seated in a chair and held the plaintiff's hands for about ten minutes, when she told the plaintiff that she was suffering with kidney trouble. She prescribed for the plaintiff, and continued to treat her, without her improving, until in October. In June, the plaintiff having experienced a crawling sensation in the lower part of her abdomen, reported it to the defendant and asked her if it could be possible that she was pregnant, and was told that she was not. Throughout the whole time the plaintiff had no periods of menstruation, but on October 19 had a slight hemorrhage, of which the defendant was notified by telephone, as well as of other conditions and symptoms; and the defendant expressed satisfaction over what she said was a return of the plaintiff's

menses, and asked her to visit her office on the following Saturday, October 23. But on Saturday morning another physician was called in, who discovered that the plaintiff was then in labor. She was removed to a hospital, where about 7 o'clock that night a fully developed dead child was taken from her with the aid of instruments.

The law is well settled in this and the court believes in all jurisdictions that a physician or surgeon is answerable for an injury to his patient resulting from want of the requisite knowledge and skill, or from the omission to use reasonable care and diligence in the treatment of the patient or to exercise such care and diligence to discover the patient's malady. Concerning the standard of knowledge and skill and the required case which the physician should possess and exercise under this rule, it is quite generally agreed that he is bound to bestow such reasonable and ordinary care, skill and diligence as physicians and surgeons in similar neighborhoods and surroundings engaged in the same general line of practice ordinarily have and exercise in like cases.

The court cannot escape the conviction that it was error to direct a verdict in favor of the defendant. By the motion therefore it was admitted that the defendant was either greatly unskilful or grossly negligent in failing to diagnose properly the plaintiff's case, and because of that, or for other reasons equally negligent or unskilful, wrongly advised her as to exercise she should take and the labor she should perform, and in addition gave her medicines of sufficient strength to produce at once pain, rigors, nausea, nervousness and other weakening and debilitating effects. It was true it did not appear what was the quality or character of the medicines prescribed; but the court thinks that in a case like this, in which the plaintiff is wholly ignorant as to such facts, when she shows the effects and consequences which the taking of the medicine produced, the burden shifts to the defendant to show that such consequences and effects were not the results of the medicine, and furthermore that the defendant, under facts similar to those here, should be called on to show that the advice given as to exercise and labor (as to continue all housework) could not and did not produce injurious results.

The court is not now called on to determine the question of whether the death of the plaintiff's child would be a proper element of damage in a suit by the mother, should the proof show it to have been brought about by the unskilful and careless treatment of the defendant.

On Regulating Practice of Optometry and Medicine

(*Price v. State (Wis.)*, 171 N. W. R. 77)

The Supreme Court of Wisconsin, in holding constitutional Section 1435 f 35 of the statutes of that state, regulating the practice of optometry, says that, although the regulation of the practice of optometry is a comparatively recent idea, upward of forty states of the Union have legislated on the subject. So far as the case of *People v. Griffith*, 280 Ill. 18, 117 N. E. 195, denies the power of the state to enact such legislation, the Supreme Court of Wisconsin is not impressed with the logic thereof. It was suggested that the Wisconsin statute was invalid because it permitted persons to select their own glasses when, as the evidence showed, harm might result therefrom. This was akin to the argument that the law regulating the practice of medicine is void because it does not prohibit the individual from buying a standard or "patent" remedy for a common ailment. At the risk of dignifying the suggestion the court will say, in the first place, that the legislature has not assumed to protect the individual from his own folly. The legislation merely aims to secure a minimum of knowledge on the part of those who hold themselves out as competent to practice optometry. In the second place, an attempt of the legislature to suppress or minimize an evil is not to be held innocuous because it does not entirely eradicate it. The law is not void because physicians and surgeons, and persons who sell spectacles without attempting to test the eyes, are exempted from its provisions. The propriety of the exemption is so manifest that discussion of the reasons therefor would be but to attempt to demonstrate the obvious.

AMERICAN SOCIETY FOR CLINICAL INVESTIGATION

Annual Meeting, held in Atlantic City, N. J., June 11, 1919

(Continued from page 715)

Desensitization in Cases of Food Idiosyncrasy

DR. OSCAR M. SCHLOSS, New York: Investigations were made on eight infants affected with idiosyncrasy to egg to determine the occurrence and duration of desensitization after the development of toxic symptoms. These observations extended over a period of from two to six and one-half years. The patients developed urticaria from one to three hours after egg was ingested. No other symptoms occurred, as a rule. Desensitization always occurred after the development of toxic symptoms. It lasted from thirty-three to forty-five days. The period varied in different infants, but was usually the same in each individual. During this time egg white could be ingested without harmful effect, and the cutaneous test to egg protein was negative. The cutaneous test to egg protein and the development of toxic symptoms after the ingestion of egg white were in close accord. The return of sensitiveness was usually abrupt. For example, on one day the cutaneous test might be negative, and the patient could eat egg white without harm; forty-eight hours later the cutaneous test might be positive and the ingestion of egg white cause severe urticaria. Two of the patients became immune at the end of one and one-half and two years, respectively. Three of the remaining six patients were desensitized by feeding with large amounts of egg protein.

Protective Power of Normal Human Serum Against Pneumococcus Infection

DR. PAUL W. CLOUGH, Baltimore: The protective power of the serum of twenty-five normal individuals was tested against infection with highly virulent strains of pneumococci belonging to Types I, II and III. Of eighteen serums tested with a Type I pneumococcus, four showed protective power. Of eighteen tested with a Type II strain, eight protected; and of nineteen tested with Type III, eight protected. If the protection tests with all three fixed types be grouped together, nineteen, or 35 per cent., showed protective power from 10 minimum lethal doses or more of culture; eleven, or 20 per cent., from 100 minimum lethal doses or more; and six, or 10 per cent., from 1,000 to 100,000 minimum lethal doses. The protective power of the most active normal serums was therefore as great as that reported in the serum of patients recovering from pneumonia, or of vaccinated individuals. In none of these serums was it possible to demonstrate the presence of agglutinins, bacteriotropins, precipitins or bacteriolysins. The protective power was manifested when the serum was injected subcutaneously and the culture later injected intraperitoneally, as well as when mixtures of culture and serum were injected intraperitoneally. No summation of protective power could be demonstrated by combining a highly protective normal serum with an artificial

immune serum. It seems probable that protective power of the serum in those normal individuals who possess it, as well as in vaccinated individuals, indicates an unusual degree of natural resistance to pneumococcus infection.

DISCUSSION

DR. RUSSELL L. CECIL, Washington, D. C.: In the study of immunity in experimental lobar pneumonia, no definite relationship could be established between active immunity and the presence of agglutinins and protective bodies in the serum. Following vaccination or an actual attack of pneumonia, monkeys may or may not develop agglutinins and protective bodies in their serum. Active immunity, however, is apparently independent of this phenomenon. Some monkeys showed definite active immunity though they possessed no protective bodies in their blood; on the contrary, certain monkeys that showed high protection in their serum failed to resist infection with the pneumococcus when it was injected intratracheally.

Relation of Pneumococcus to H-Ion Concentration, Acid Death Point and Dissolution of Organism

DRS. FREDERICK T. LORD and ROBERT N. NYE, Boston. In the growth and death of the pneumococcus in fluid medium containing 1 per cent. of glucose the production of acid is the most important bactericidal factor. One per cent. glucose bouillon cultures of the pneumococcus allowed to grow and die out usually reach a final acidity of a pH of about 5.1. At a H-ion concentration of about 5.1 or higher, the pneumococcus does not survive longer than a few hours; in H-ion concentrations of from 6.8 to 7.4 per cent. The pneumococcus may live for at least many days. In the intervening H-ion concentrations, between 6.8 and 5.1, the pneumococcus is usually killed with a rapidity which bears a direct relation to the H-ion concentration; that is, the greater the acidity the more rapid the death. Cloudy suspensions of washed pneumococci in H-ion concentrations varying from 8.0 to 4.0 show, after incubation, dissolution of organisms in lower H-ion concentrations than about 5.0. This dissolution is most marked at from 5.0 to 6.0. Some dissolution also takes place toward the more alkaline end of the scale. No dissolution occurs at the most acid end of the scale.

Comparison of Medical Casualties Among British and American Troops in General Hospital in France

DRS. REGINALD FITZ and ALICE CUNNINGHAM, Boston: A statistical comparison was made of the common diseases occurring in British and American troops who were admitted to U. S. Army Base Hospital No. 5 from Flanders and northern France during 1918. Each body of men tended to have the same common illnesses, but in different proportions. The British had many cases of trench fever and trench nephritis. These diseases were comparatively uncommon among the Americans. The Americans had many casualties from diarrhea and indigestion, while the British suffered from casualties due to physical strain and fatigue. The Americans more than the British seemed to develop an acute exacerbation of any chronic or latent disease to which they had any tendency from inheritance or previous history. These differences were in part due to the facts that a certain number of men constitutionally unfit to military life had not been weeded out from the Americans at the outset and that there were too few officers and noncommissioned officers who were trained to enforce the disciplinary and hygienic measures designed to keep medical casualties as small as possible.

Management of Postpneumonic Empyema

DR. WILLARD J. STONE, Toledo, Ohio: Among eighty-five patients with empyema on whom operation was performed as soon as the empyema was diagnosed, the mortality was 61.2 per cent. Among 190 patients on whom late operation was performed for empyema, that is, following a series of preliminary aspirations and after subsidence of the acute pneumonic process, the mortality was 12.6 per cent. In the last ninety-four operations the mortality following this plan of procedure was 9.5 per cent. Although types of infection with varying virulence may have accounted for the decreased mortality, it is believed that operation prior to the subsidence of

the acute pneumonia, and before adhesions have immobilized the mediastinum, is accompanied with greatly increased risk. In both those operated on early and those operated on late the infectious agent was found to be a hemolytic streptococcus in more than 70 per cent. of the cases. The late operation showed a much greater percentage of recoveries for streptococcus infection than the early operation. After adhesions have limited the mobility of the mediastinum, the pressure changes incident to an open pneumothorax do not affect, to so great a degree, the opposite lung, and operation may be performed with greater safety. Preliminary aspirations were performed every day or alternate day to remove the pus. The late operation was performed from the twelfth to the fifteenth day and was usually done under local anesthesia. A Brewer tube, to which was attached an Ewald bulb for suction, was used. Surgical solution of chlorinated soda (Dakin's solution) was used as an irrigating fluid through a Carrel tube which was passed through the flanges of the Brewer tube. The five most common complications after operation, as a cause of death, were, in order of frequency, nephritis, pericarditis (usually purulent), peritonitis, substernal pus pockets, and lung abscesses. In the patients on whom early operation was performed, an active pneumonia was usually found to be present in both lungs.

Harmful Effects of Shallow Breathing

DR. JOHN C. MEAKINS, Montreal: It has been shown by Haldane, Meakins and Priestley that rapid, shallow breathing leads to anoxemia, and also that one of the effects of anoxemia may be the production of this type of breathing. Therefore, under certain circumstances a vicious circle may be established. There is a clear relationship between the respiratory rate and the cyanosis which is undoubtedly due to anoxemia in acute pneumonia. As the respiratory rate increases the volume per respiration decreases, and the total ventilation per minute rises above normal. If the respiratory rate increases beyond 50 per minute, cyanosis is likely to appear. If this extreme rate persists, cyanosis gradually increases until the cardiovascular system eventually begins to fail. The respiratory rate and the cyanosis are not necessarily dependent on the extent of pulmonary involvement; it may be extreme, when there is evidence of comparatively slight consolidation, and may not appear even when the greater part of one lung is evidently consolidated. Another point which must be taken into consideration is that of the quantity of blood which may be circulating through the consolidated area. It has been shown by Gross that this may be considerable. Such blood is not oxygenated, and joins the mixed arterial blood to produce a general diminution of the total oxygen content of the circulating blood. This may play a comparatively small rôle in the production of cyanosis. The fact remains, however, that when crisis occurs, and the respiratory rate diminishes, the cyanosis disappears in spite of the fact that the consolidation remains some time. Therefore it may be concluded that rapid, shallow breathing occurring in pneumonia is a very dangerous condition in consequence of the anoxemia which results from it.

Clinical Significance of the Suprarenal or Other Endocrine Glands in Influenza and Influenzal Pneumonia

DRS. D. M. COWIE and P. D. BEAVEN, Ann Arbor, Mich.: Being unable to convince ourselves that there was any serious cardiovascular disturbance in the large majority of cases of influenza and influenzal pneumonia to explain the marked asthenia and low blood pressure, we became interested in the possibility of suprarenal dysfunction or some other endocrine disturbance being responsible for this group of symptoms. Necropsy reports reveal hypoplasia of the suprarenals and evidence of suprarenal dysfunction. The appearance of suprarenal dysfunction in influenza and influenzal pneumonia is suggested clinically by the cardinal symptoms: a characteristic rise in blood pressure following the prolonged administration of epinephrin, the prolonged blood pressure curve following the administration of 1 mg. of epinephrin. That an endocrine disturbance is present in influenzal pneumonia is further suggested by a prolonged blood sugar curve after injection of epinephrin, and a prolonged

blood sugar curve after ingestion of glucose. Hypoglycemia is not present in influenza and influenzal pneumonia as has been found to be the case in some diseases of endocrine origin. If epinephrin is of any use in the treatment of the symptoms of suprarenal dysfunction, the proper method of administering the epinephrin seems not yet to have been found.

DISCUSSION

DR. FRANCIS G. BLAKE, Washington, D. C.: In a series of about 250 necropsies of cases of influenzal pneumonia at Camp Pike, two cases with markedly hemorrhagic suprarenal glands were noted.

DR. E. C. ROSENOW, Rochester, Minn.: In connection with Dr. Cowie's clinical observations, it is of interest to note that guinea-pigs injected with the strains from typical cases of influenza commonly showed swelling, edema and hemorrhage of the suprarenals. This was particularly marked in the case of some strains.

DR. C. P. HOWARD, Iowa City: We, too, were struck with the profound prostration and weak pulse in these cases, and were much interested in being told by our pathologists that in one or two cases there was some abnormality in the suprarenals. Might this not also explain the absence of a leukocytosis in this disease, as we have shown elsewhere that in polyglandular insufficiency there is an absence of the normal leukocytic response to the subcutaneous injection of epinephrin?

(To be continued)

AMERICAN ORTHOPEDIC ASSOCIATION

Thirty-Third Annual Meeting, Atlantic City, N. J., June 14-17, 1919

(Concluded from page 718)

Personal Experience with Lane's Plate in Fractures

DR. PAUL P. SWEET, Hartford, Conn.: Among 1,500 fractures of the long bones observed during a three year period, there were 172 open operations; forty-one for compound fractures, and 129 for reduction of simple fracture, and delayed, nonunion or vicious union. Lane plates were applied in twenty-eight instances. Primary healing of the operative wound was obtained in every case except two compound fractures with severe displacement. Excellent final results were obtained, however, in spite of this risk. In four cases, sinuses developed after some weeks. On removal of the plates, the sinuses closed, except in one instance in which a low grade osteomyelitis was caused by the plate. The plates and screws in this instance had been handled by the operator. The patients were all urged to have the plates removed after firm union had taken place, and this was done in four instances. No abnormal bony reaction or tissue reaction had been found. In one case a plate was placed on the femur eighteen months after the fracture, and the result was excellent. Probably removal of considerable bone, and apposition of healthy nonseptic fragments, explained this success. The cases of sinus all occurred in the radius and ulna, or tibia and fibula; there was no trouble in any of the femur cases. It seems, then, that Lane plates offer a satisfactory means of fixation in selected cases. They are more efficient than other agents in highly comminuted fractures, when other fixation materials may increase the trauma.

Points to Be Observed in the First Ten Days of the Treatment of Compound Fractures

DR. H. WINNETT ORR, Lincoln, Neb.: I wish to insist on immediate or very early restoration of parts in a compound fracture to as nearly a normal position as possible. Following these methods of fixation which actually do maintain position with length and in which the immobilization is as perfect as possible, experience of the war hospitals has shown that in femurs the practical use of the Thomas splint and plaster of Paris, either or both in some cases, may be made to meet practically every indication. In leg fracture the same thing is true (with a wider field of use for plaster of Paris). In fractures of the upper arm there has been a tendency for too long continued use of the long Thomas splint. The importance of elbow flexion and supination of

the hand, to be done not later than two weeks from the time of injury, must be emphasized, especially in fractures of the humerus. Plaster of Paris may also be of the greatest use in these cases. Supination in a Balkan frame in all of these fractures is frequently important and necessary, but the use of weights and pulleys in this connection should not be confused with the occasional use of weights and pulleys for traction, which should certainly be used much less than heretofore.

Disability Following Injuries to the Back in Industrial Accidents

DR. JAMES WARREN SEVER, Boston: Persons suffering injury to the back in industrial occupations suffer long periods of disability. Two facts are noted in these cases: first, that the disability is unusually long, and secondly that medical supervision is not of the best, nor calculated to get the best results. Among 134 cases the average period of disability was about six months. These figures cover the time elapsed from the accident, until seen by me as an impartial examiner for the Industrial Accident Board. In some cases we believed that the man should try and go back to work, but there is no doubt a psychologic factor in many cases. While one cannot say that any are real malingerers, the fact that they receive compensation without working has a good deal to do with disability in many cases. There is no doubt that if proper and skilful medical attention had been given, the disability periods would have been cut in half.

DISCUSSION

DR. COMPTON REILLY, Baltimore: This problem is very difficult from the insurance point of view, and as to how long these people should be compensated. I feel, as Dr. Sever does, that many of these men would go back to work much more quickly if there were no question of compensation.

DR. C. S. BALDWIN, Salt Lake City: Early diagnosis of these cases is important. One important point is putting them up on an inclined plane with a Sayre extension apparatus. These injuries result in fracture and displacement of the articulatory surfaces of the bodies of the vertebrae.

Application of Curative Therapy in the Ward

DR. HENRY CHASE MARBLE, Boston: All forms of therapy are united to one end, under a competent surgeon, who can pool his resources to achieve a successful whole. Nurses, orderlies and aides are at his disposal. The latter, working under the direction of the ward surgeon, strive, through simple and graded occupation, first for mental rehabilitation, and secondly for restored function. Direction of a medical officer is necessary so that the correct amount and type of work may be given. Often men most in need of occupation are the hardest to start. Rarely does a man do more than necessary and have to be slowed down. When the patient is up in a wheel chair or about on crutches, some attempt can be made, under careful supervision, toward functional restoration. The required time should be given to occupational therapy, or it fails in its purpose. Physiotherapy ward work is of another type. The aide, under supervision of the medical officer, endeavors to prevent deformity and to stimulate motion. Careful records are kept of improvement. The barometer of motion is always pain. The type of occupational work most suitable is rug making, toy making, weaving, stenciling, printing and bead weaving.

DISCUSSION

DR. ALBERT H. FREIBERG, Cincinnati: It is possible for a human being to re-establish himself without any outside agency. A man should expect help from industry as his heritage; the cripple is going to be better looked after than formerly because of the scientific way in which this question will be treated as the outcome of the war. It depends a great deal on the individual whether he can accomplish big things in spite of his handicap. There is not as yet a completely developed system which can be used as a future textbook, because no one has as yet taken charge of this side of the work. Certain things should be recorded as fundamental, and a systematic arrangement of the therapeutic ideas on the subject should be made under proper supervision of medical men. Any other way is quackery.

DR. JOEL GOLDTHWAITE, Boston: In France, the physical and occupational aides were expected to know both branches. In Boston, a regular curriculum on occupation therapy has been started, so that it will be possible to go there and get a person trained in the particular work wanted.

DR. JOHN L. PORTER, Chicago: From the attitude of the workers and the instructors, the curative side of occupational therapy is likely to be lost to sight. Vocational therapy has a distinct value in keeping the men occupied mentally, but the vocational end does not amount to much. We have had everything taught from handwriting to animal industry, chicken raising and typewriting, but most of the men want to go back to the occupations they had before. A valuable side of curative therapy is the physical end of it.

*Nutrition of Fetus. J. M. Slemmons, New Haven.—p. 194.

Preoperative and Postoperative Blood Pressures.—Polak urges that complete records be made of kidney function and blood pressure in every case before deciding on operation. He has such records of more than 350 consecutive abdominal cases and feels justified in drawing the following conclusions: The pulse pressure is the test of the muscular strength of the individual woman's heart, when endocardial lesions can be excluded. The index of the muscle competency is shown by the relation of the pulse pressure to the systolic pressure which should be as 1 to 3 or more, if the compensation is adequate. The efficiency of the kidney function is directly dependent on the cardiac force of the individual, provided the kidney structures are normal or approximate the normal. Ether anesthesia of one hour's duration does not disturb the relation of the pulse pressure to kidney function, unless the operation is accompanied by considerable loss of blood. When the preoperative kidney function is low, the pulse pressure must be relatively high to compensate for the deficiency, for it does no good to add saline by skin or bowel or by infusion, unless there is sufficient cardiac strength to take it up and carry the column along. When both the pulse pressure and the "phthalein" output are low, or the relation of the pulse pressure to the systolic pressure is as 1 to 2, the operative prognosis should be guarded. Morphine, in large doses, used during operation, seems to help in diminishing the shock, but has a definite effect in diminishing the kidney output. In the majority of cases there is a moderate fall in both the systolic and diastolic blood pressure following ether anesthesia; the inhalation of oxygen after the withdrawal of the ether diminishes this fall, but its effect is only transient. In

cases of shock, especially where there has been much blood lost during the operation, the fall in systolic pressure is greater than after a long operation without blood loss. The pulse pressure is a better index of hemorrhage or cardiac failure than the systolic pressure, and finally, there is a constant rise in the leukocyte count in the presence of actual hemorrhage, while the leukocytes fall in shock.

Inversion of Uterus.—In Boyd's opinion hysterectomy is indicated when there exists gangrene or marked infection or a tumor of the uterus, but in clean cases it is unjustifiable. In the acute case, before involution is completed, the uterine musculature is still hypertrophied. It is pliable and will often yield to taxis. Manual reposition should, therefore, be tried in all such cases, but after a month or six weeks the uterus will have returned to its normal size and the tissues become firm and unyielding. In these chronic cases, manual reposition should only be carried out for a short time, if at all. By early operative measures, mortality and the comfort of the patient will be materially improved. Colpohysterotomy is, therefore, the operation of choice in the treatment of difficult cases. It is conservative, simple of execution and can practically be applied to all. Should the anterior operation fail, the posterior wall of the uterus could also be incised. This would undoubtedly make it possible to reposit the uterus. Anterior colpohysterotomy, the Spinelli operation, has certain advantages over the posterior. The field for operation is more accessible and suturing is facilitated.

Restoration of Rectovaginal Septum.—The operation advocated by Koster was devised by the late Dr. Frederick Weisbrod at the Wyckoff Heights hospital, Brooklyn, about fifteen years ago.

Corpus Luteum Extract in Vomiting of Pregnancy.—Quigley treated seventeen patients; twelve were benefited permanently; four had a relapse, and in one case the treatment was a complete failure. The average number of doses was seven; the dose, 0.2 gm., desiccated substance of the gland.

Nutrition of Fetus.—Slemmons says that there is no diet specifically adapted to the state of pregnancy; the prospective mother may exercise the same freedom in the selection of food as any one else. She should, however, choose what will agree with her and avoid that which she cannot digest and assimilate. In a practical sense the quantity of the mother's food is more influential than its quality. Popular opinion holds that during pregnancy the mother "should eat for two." This doctrine is erroneous. A diet which has previously been ample will likewise be sufficient throughout pregnancy. And, it is not unimportant to emphasize this view, which has the unqualified support of painstaking, scientific investigations, because overeating during pregnancy is much more likely to provoke discomfort than insufficient nourishment. On the other hand, there can be no justification for measures intended to restrict the growth of the fetus, for when rigidly carried out they tend to weaken the mother. She may be careful, in other words, to avoid overgrowth of the fetus but should not adopt a diet so limited as to interfere with normal development. So long as her health is properly maintained, no thought may be given as to what the size of the fetus is likely to be. At present, provided the physician determines by a thorough, preliminary examination the existence of any disproportion between the size of the fetus and the capacity of the mother's pelvis, he is qualified to decide what the appropriate treatment should be in order to bring pregnancy to a successful termination.

Pulmonary Sequels Following Influenza. W. D. Tewksbury, Washington, D. C.—p. 375.

Influenza at Tuberculosis Sanatorium.—This study of fourteen cases made by Amberson and Peters shows that not only is influenza likely to attack tuberculous sanatorium patients as severely as other individuals, given the necessary conditions of contact and exposure, but its results are likely to be particularly grave in those with massive pulmonary lesions and little pulmonary reserve. It seems likely that a not inconsiderable proportion of individuals with pulmonary tuberculosis suffer exacerbations or relapses as a result of this intercurrent infection. In further support of this view, in taking the histories of patients recently entering the sanatorium, the authors met with a fair number of cases in which the development or exacerbation of manifest tuberculosis followed so soon after an attack of influenza that the causal relationship was very evident.

Reactivation of Tuberculosis by Influenza.—Of thirteen cases of healed and quiescent pulmonary tuberculosis under observation for weeks, presenting at no time evidence of moisture, six cases, or approximately 50 per cent, showed a reactivation and a positive sputum after an attack of influenza. All thirteen influenza convalescents presented evidence of moisture on an average of six weeks after dismissal from the hospital. The râles were of two distinct varieties and because they complicated an already existing healed tuberculous focus they were confusing. The coarse moist râle, abundantly present in all cases, was not unusual and was easily explained. It was the rather typical râle found in many postpneumonic and bronchitic infiltrations, distributed over the entire surface of the lung, most pronounced, perhaps, peribronchially and basally. The interesting and complex finding, also present in all thirteen cases, was a fine moist râle. This râle, except in one or two cases, was confined to an apex or to both apices, and was entirely absent over the bronchi and at the bases. It occurred singly and in showers. Beginning with inspiration, these râles, forming a crescentic shower, covered the entire respiratory cycle. They were in large part unaffected by cough and in some cases augmented by cough and never dispersed, so that fine moist râles were restricted to an apex, occurring in showers, very constant and unaffected by cough. To make the picture simulate still more an active pulmonary tuberculosis, the physical signs of the preexisting healed lesion were present in the same area. And finally, the patient almost invariably had a fever and presented the usual corresponding signs of toxicity. Repeated observations at one week intervals, added one more disturbing element, that of constancy and persistency of symptoms and findings. In two cases which proved nontuberculous, the findings were present for eight weeks.

Pulmonary Sequels of Influenza.—Tewksbury is of the opinion that there will probably be an increase in active tuberculosis due directly to the influenza epidemic. He finds that the type of tuberculosis following influenza seems to respond especially well to pneumothorax treatment.

Experimental Hydrocephalus.—Experiments were made by Dandy on dogs for the purpose of studying the development of internal hydrocephalus. They showed that hydrocephalus has been produced by placing an obstruction in the aqueduct of Sylvius. Dilatation of the third and both lateral ventricles results. In one case the foramen of Monro was occluded; this was followed by a unilateral hydrocephalus. If the choroid plexus of one lateral ventricle is completely removed at the time the foramen of Monro is occluded, not only does no dilatation occur, but the entire lateral ventricle collapses. This is the only absolute proof that the cerebrospinal fluid is formed from the choroid plexus. At the same time, it proves that the ependyma does not secrete cerebrospinal fluid. If the choroid plexus of both lateral ventricles is removed, and an obstruction is placed in the aqueduct of Sylvius, hydrocephalus still results in the third and both lateral ventricles, but at a reduced rate. The fluid forms from the choroid plexus of the third ventricle but cannot escape into the subarachnoid space. Cerebrospinal fluid forms in all the cerebral ventricles. It is absorbed almost entirely in the subarachnoid space. The sole communication between the ventricular system and the subarachnoid space is through the foramina of Luschka and the median foramen of Magendie. The phenolsulph-naphthalin test will prove conclusively whether the foramina of Luschka and Magendie are open or closed. Closure of these foramina invariably causes hydrocephalus. Hydrocephalus follows ligation of the vena magna Galeni if the ligature is placed at the origin of this vein. Ligatures beyond or in the sinus rectus have no effect because there is sufficient venous collateral circulation. The communicating type of hydrocephalus has been produced in dogs by a perimesencephalic band of gauze, saturated in an irritant which induces adhesions. This obstruction prevents cerebrospinal fluid from reaching the cerebral subarachnoid space where most of the cerebrospinal fluid is absorbed. The resultant diminished absorption of fluid results from hydrocephalus. Hydrocephalus follows ligation of the great vein of Galen because of an overproduction of the cerebrospinal fluid. In other types of hydrocephalus, both obstructive and communicating, the accumulation of fluid is due to a diminished absorption of cerebrospinal fluid.

Traumatic Facial Diplegia.—Ransohoff reviews the literature and records one personal case in which the lesion on each side was in the fallopian canal, below the geniculate ganglion, and at a point above where the chorda tympani is given off. It was also below the point where the nerve to the stapedius is given off, since there is no record of hyperacusis. Although there was a fracture across the base of the skull, through the mastoid and petrous portion of the temporal bones, as shown by the ecchymosis behind the ear, neither nerve was severed. Of the right nerve one can be sure of this, since the paralysis did not manifest itself until two days after the injury. Hemorrhage only could have accounted for this late occurrence. On the left side the paralysis was instantaneous, but since it completely and speedily recovered, it is likely that here also there was only a contusion with hemorrhage. Traumatic facial diplegia is an exceedingly rare condition. Ransohoff has been able to get only four other cases from the literature. All of

the patients recovered. In none of the cases was a decompressive operation indicated in the judgment of the surgeons in charge.

Clinical Study of Nerve Anastomosis.—This paper represents the results of forty-one cases of nerve anastomoses performed in the Mayo Clinic up to Jan. 1, 1917. Cases in which postoperative records are shorter than sixteen months are not included in the report. Nine facial anastomoses were made of 89 per cent. Of the patients heard from, all of whom had improved, the average amount of improvement was 71 per cent., and in this group there were no failures nor indeterminate results, no infections and no deaths. Seven ulnar anastomoses were made. The amount of maximum improvement in the patients who reported was 63 per cent. of the sensory, motor and trophic functions. There were no failures nor indeterminate results, no infections and no deaths. One radial anastomosis was made. No report has been obtained from this patient since he left the clinic. Seven median nerves were repaired. Six (85.7 per cent.) of these patients have been heard from, or have been studied following operation. The average time before maximum improvement was reached was twenty-one months, with 72 per cent. return of the sensory, motor and trophic functions. There was one failure, no indeterminate results, no infections and no deaths. Ten musculospiral anastomoses were done. Nine (90 per cent.) were heard from after operation. The average time before improvement was noticed was twelve months; the average time before maximum improvement was noted was twenty-seven months. The amount of improvement in the patients benefited was 72 per cent. of the sensory, motor and trophic functions. Twenty per cent. only of these patients were improved; in 30 per cent. the results were indeterminate, and in 50 per cent. they were failures. In one case the wound became infected. There were no deaths. Four external popliteal anastomoses were made. The average time before improvement was noticed was eleven months; the average time before maximum improvement was reached was approximately twenty-four months. The average improvement obtained was 43 per cent. return of the sensory, 30 per cent. of the motor, and 80 per cent. of trophic function. In one case the result was a failure (infection) and in another the result was indefinite. Two sciatic nerves were repaired. One of the two patients was heard from following operation; he reported 40 per cent. return of the sensory, motor and trophic functions. One right recurrent laryngeal nerve was anastomosed. Improvement was first noticed twelve months after the operation; maximum improvement—90 per cent. return of the motor function—was reached at the end of thirty-six months. Adson points out that the degree of regeneration depends on (a) duration of time between injury and repair, the shorter the period the greater the regeneration. The possibility of regeneration is very slight after three or four years, (b) actual loss of nerve tissue, and (c) retraction of severed ends. In the technique of nerve repair (a) no covering is necessary if the freshened ends can be sutured in close apposition; (b) if an intervening gap remains it should be utilized; preferably by fascia; (c) if the gap is longer than 5 cm. tendon transplantation and arthrodesis should be considered instead of nerve anastomosis; (d) autogenous transplants may be considered for short gaps, but they are of no greater value than utilization; (e) in all technique, the wound should be free from hemorrhage and infection and the nerve ends should not be traumatized; and (f) during the postoperative convalescence, the paralyzed muscles should be massaged and passive motion should be administered.

Unilateral Renal Tuberculosis. Herman cites a case of primary tuberculosis of the urinary bladder. The patient, a woman, aged 30 years, complained of burning on urination and pain in the upper abdomen and back. The cystoscopic examination disclosed the presence of ulcerations typical of tuberculosis. The ureters and kidneys were examined and found negative for tuberculosis.

Operation for Dupuytren's Contracture. Under general anesthesia, without the use of a tourniquet Gill makes a transverse incision along the distal palmar crease. Through

this incision alone a careful dissection is made of the entire palmar fascia to or beyond the crease at the base of the thenar eminence, as far toward the base of the palm as is necessary, and to the web of the fingers. The skin is adherent to the fascia, and the dissection must be made carefully to avoid buttonholing the skin. With proper retraction, as the dissection proceeds, it is found that the entire fascia can be exposed and freed within the limits mentioned. The contracted fascia is then excised without injury to the underlying tendons, vessels and nerves. The tendons do not require lengthening as they do not participate in the contracture. If contracted fascia is present on the palmar aspect of the proximal phalanges, it may be excised through transverse incisions along the crease at the base of each finger involved. If, now, it is found that the proximal interphalangeal joint cannot be extended, or that it can be extended and flexed again only with a snap, the head of the first phalanx must be excised through a transverse dorsal incision over the joint. A small free fat transplant from the thigh is inserted smoothly beneath the palmar skin. It will lie in position without sutures. It is placed here to prevent subsequent adhesion of the skin to the tendons and to reconstruct the normal softness and plumpness of the palm of the hand. The incision is closed with a few interrupted sutures of No. 0 chromicized catgut. The hand is dressed on a well padded splint for a week.

Consecutive or Interrupted Hospital Training for Pupil Nurses.—Worcester defends the plan of nurses' training adopted by the Waltham Training School for Nurses, which believes that it is an educational advantage to interrupt the hospital training of its pupils by a few months of training in home nursing.

Torsion of Spermatic Cord.—According to Slute the diagnosis of torsion of the spermatic cord should not be difficult. In acute complete torsion of the cord, the onset is very sudden with severe pain in the testis. This pain often radiates along the inguinal canal and may radiate down the thigh or into the pelvis. Vomiting often occurs at the onset, but does not persist. More or less shock and prostration is present at first. Fever does not occur early but one or two degrees may be present later in the course of the condition. The testis is tender soon after the onset. After twelve or eighteen hours the scrotum becomes slightly red-hot, swollen and very tender on the affected side. Edema of the skin was present in two of Clute's cases. The epididymis may be palpated in front of the testis, especially if the case is seen early. In cases seen several days after the onset, the relations of testis and epididymis cannot be defined because of their swelling and the presence of some degree of hydrocele. The spermatic cord in the inguinal canal is neither enlarged nor tender, except near the point of torsion. The prostate and seminal vesicles are negative to rectal examination. In partial torsion of the cord the symptoms are similar but less severe. Recurrent attacks of pain occur in the testis, followed by slight swelling of the scrotum. The pain is often mild and of a relatively short duration. Vomiting and fever are unusual. In any case after detorsion, the symptoms disappear as quickly as they arise. Untreated, the pain, tenderness and swelling persist for many days. The treatment of torsion of the cord depends on whether or not the testis is fully descended and on the duration of the torsion. In any case seen shortly after the onset of the symptoms, detorsion should be attempted. Since the usual direction of the twist is from within outward and forward, the reverse should first be attempted. Increasing pain demands that an attempt to turn the testis in the other

direction be made. If detorsion cannot be done, an operation is necessary. In fully descended testes, an incision is made in the scrotum and the tunica vaginalis opened. An attempt is made to untwist the cord and to restore the circulation to the testis by the application of hot towels. If the case is not seen early, this attempt will fail. Orchidectomy should then be performed. The best treatment for torsion of an undescended testicle is orchidectomy. If, for any reason, this cannot be done, a plastic operation returning the testis to the scrotum, if possible, and at least fixing it to prevent future twists, is indicated.

Present Psychologic Scales.—Pressey and Cole report the study of the psychologic examination of fifty normal children and 110 feeble-minded children and 115 adults of feeble-minded grade, all grading on the scale between the ages of 8 and 12. The major purpose was to determine the applicability of the present psychologic scales to work with adult individuals. In connection with this a comparison of normal and feeble-minded children was made to obtain some evidence as to the distinctive features of the defective mentality. Individuals more than 20 years of age show a definitely greater irregularity on a psychologic scale than do normal or feeble-minded children. Feeble-minded children are not distinguished from normal children by greater irregularity. The feeble-minded show an examination of a makeup different from that given by normal children. In general, the mentally defective show a better sensorimotor ability than normal children of the same mental age, but a smaller number of ideas and a poorer ability for the recombination and use in a new situation. Adult individuals again give a result distinctly different. The strikingly different makeup of the examination given by the adult individual is used as an argument, (a) for the use of the "intelligence quotient" or "coefficient of intelligence" as a form of expression for the results of the psychologic examination and (b) for the development of methods and tests especially adapted for use with adults.

Lethargic Encephalitis.—The highly interesting point in relation to the case cited by Stafford is in regard to the bacteriologic findings of the specimens of spinal fluid. A smear of the centrifugized sediment of the first puncture showed, in addition to lymphocytes, a number of rather large diplococci. Cultures were made on ascitic agar, Loeffler's medium, blood agar, and in ascitic broth, but with negative results. The fluid from the second spinal puncture also showed, under the microscope, this same diplococcus, but cultural attempts in these same aforementioned mediums were likewise negative. In an endeavor to secure a culture at any cost, both the first and second specimens of spinal fluid were placed in the incubator overnight at 37.5 C. The following morning numerous minute flocculi were observed throughout both tubes. They were placed in the centrifuge and thrown down. By inoculating ascitic agar slants with this centrifugized sediment a sparse growth was obtained, which increased as it was transplanted repeatedly. The organism grows rather poorly on plain agar. The colonies on this medium resemble streptococcus colonies, except that they are more delicate and slightly smaller. The organism is a gram-positive diplococcus, frequently occurring in short chains of three or four loosely joined cocci. It stains, but rather poorly, with all common laboratory dyes, some organisms being deeply stained and others slightly. It produces no capsule. In smears from forty-eight hour cultures, it was observed that the chains show a tendency to divide longitudinally, i. e., a distinct and continuous cleavage can be noted, extending throughout the length of the short chain of cocci. This probably accounts for the clusters of organisms, resembling staphylococci, which are commonly encountered in smears from older cultures. Growth on blood agar plates did not produce any hemolyzed areas or greenish zones. The inoculation of a guinea-pig intracardially with one half the growth on an ascitic agar slant failed to produce any ill effects. A rabbit, inoculated intravenously with two large doses, seven days apart, the first consisting of the growth of one ascitic agar slant suspended in physiologic sodium chloride solution and the second, the suspended growth of three agar slants, apparently developed no illness, but the presence of agglutinins was demonstrated. Another rabbit inoculated intraspinally with the growth from an ascitic agar tube suspended in physiologic sodium chloride solution showed no ill effects.

Antipneumococcus Serum in Influenzal Pneumonia.—Polyvalent antipneumococcus serum was administered at Camp Greene in 158 cases of pneumonia, the cases being selected according to two principles. In all Type I cases the patients received serum unless from their condition when type determination was heard from it was judged that the patient could be expected to recover without serum. In certain severe cases where there was danger of an unfavorable outcome, Brown and Palfrey considered themselves justified in giving the patients the benefit of the possibility of improvement by serum treatment without waiting for type determination. Of the pure Type I cases, there were 113, and twelve men died, a mortality of 10.6 per cent. Of the total cases where pneumococcus Type I was present either alone or associated with another type, there were 133 cases and thirteen deaths, a mortality of 9.7 per cent. Serum was given in doses of from 100 to 150 c.c., intravenously, repeating at eight, twelve and sometimes twenty-four hour intervals according to response on the part of the patient. In certain cases one dose seemed to be sufficient to turn the tide toward recovery; other cases required one or more repetitions. The largest amount given in any single case was 600 c.c.; however, the average amount given was 300 c.c. The possibility is at least suggested that the non-specific foreign protein reaction may serve to some extent to stimulate reaction against infection.

Action of Antipyretic Analgesics on Psychologic Reaction Time.—A careful study and analysis of all the data obtained has led Macht and his associates to the following conclusions: The results obtained with antipyretics are quite different from those found after morphin or opium. No primary stage of stimulation or shortened reaction time was noted after administration of antipyretics, except possibly after small doses of quinin. It was found that in all cases the ordinary doses of antipyretics produced either very little effect on the reaction time, or if affecting it at all, they always impaired it as indicated by the prolongation of the mean readings, by the increase in the mean variations of readings, or by both. The most powerful or depressant drug in this respect was found to be pyramidon. It was furthermore interesting to note that when the antipyretics exerted an influence on the reaction time, the simple reflexes or reactions to sound, light and touch were more prolonged or impaired than the more complex association tests. Of the three simple reactions that of touch was more generally retarded than that of sound or light. The association tests were also depressed or impaired, but usually in a distinctly lesser degree than the simple reactions or reflexes. Experiments with combinations of the various antipyretics gave results which could be explained by a simple summation or addition of the individual effects of the components. No so-called synergism or potentiation of one drug by another was observed. The curious difference in the effect of the drugs on the simple reactions as compared with that on the more complex ones is the direct opposite of the results obtained after administration of opium or morphin. In the latter case, the simple reactions were always less impaired than the more complex association tests. A comparison of the findings obtained with the two groups of analgesics, the opiates or narcotics, and the antipyretic analgesics, seems to point to some lower synapse as the seat of action of the coal tar derivatives.

Angioneurotic Edema.—Austrian emphasizes that angioneurotic edema is a symptom and not a disease, and to show that in those cases in which the immediate cause of this manifestation can be discovered and removed, the symptom can be relieved. In one case the symptoms were the result of sensitiveness to ham; another patient reacted to white beans, another to fish, another to veal, and a fourth to strawberries.

Acute Pancreatitis.—Bloodgood adds two cases to nine others seen by him during the past twenty-five years. He is convinced that drainage of the lesser peritoneal cavity through the gastrocolic omentum meets the indications more than any other suggested treatment. The best method of examining the pancreas, if one does not wish to go through the gastrocolic omentum and fat without more evident signs, is to withdraw the omentum and colon and inspect and palpate the pancreas through the mesocolon.

Acute Diverticulitis of Transverse Colon.—In the case reported by Vellacott the patient, a woman, aged 36 years, had been subject to attacks of pain in the upper abdomen for about eighteen months. This pain was severe at times, but had no relation to food though she had to be careful what she ate. On the day of admission she "had had indigestion all day," which developed into acute pain quite suddenly about 5 p. m. Vomiting and the signs of acute appendicitis were all present except that the maximum tenderness and rigidity were situated to the right of and close to the umbilicus, nevertheless the diagnosis of appendicitis was made. At operation considerable free fluid was present in the abdomen with a faint smell of *B. coli*. The appendix was seen to have been the seat of former disease, but was obviously not the cause of the present attack. Adherent to the transverse colon, lying in relation to the second part of the duodenum, was a small amount of "lymph" and a mass the size of a large walnut was felt in its upper and posterior wall. The omentum was wrapped round this. From the mass a thick band passed up into the transverse mesocolon toward the central group of lymph glands. This band and the mass in the bowel were so hard that Vellacott diagnosed malignant disease with perforation and decided to resect.

About 6 inches of the gut were accordingly resected and an end-to-end union made. On examining the part removed Vellacott could find no trace of malignant disease in the lumen of the gut, but on the upper posterior wall was a small opening, an eighth of an inch wide, leading to a cavity in the hard mass. This cavity was a little more than a quarter of an inch in diameter and was filled by a concretion which could be seen from the lumen of the gut. A perforation had taken place from the diverticulum forward into the general peritoneal cavity in front of the transverse mesocolon. The case is of interest as occurring in the transverse colon and at the early age of 36.

Clarification of Turbid River Waters with Alum.—The main conclusions reached by Raju as a result of his observations are that with increasing doses of alum there is a progressive improvement in the color and transparency of turbid water until the point of perfect clarification is reached. In no case was any evidence obtained of a negative phase or a retardation of settlement with overdoses of alum; and in no case was any evidence obtained of the existence of a positive association between the alkalinity and the dose of alum required. All the waters examined had, however, sufficient amount of carbonates to react with at least seven or eight parts of aluminium sulphate per hundred thousand.

Sugar of Blood and Urine.—McKay found that the threshold stimulus of the kidney for sugar excretion varies widely in different individuals and in the same individual under different circumstances. Glycosurics are met with in whom (1) the threshold is high, usually the condition seen in the fat. Overfed classes; (2) the threshold is low, as in (a) the latter stages of (1); (b) those who have lost the power of storing, oxidizing and converting sugar into fat; (c) those who present an excessive permeability of the kidney to sugar as a result of oxaluria, gout, stone. The limits of the normal variations of the sugar of the urine of Bengalis are from 0.015 per cent. to 15 per cent., the average being 0.065 per cent. No parallelism or arithmetic proportions exist between the concentration of the sugar of the blood and that of the urine in any of the following conditions: (1) normal health; (2) a glycosuric diabetes; (3) varying degrees of glycosuria in different individuals; (4) varying degrees of glycosuria in the same individual. The ingestion of glucose is always followed by an increase in the sugar of the urine, whether the concentration of the sugar of the blood increases or not, i. e., in the healthy potential diabetes and diabetics. Kidney disease may prevent glycosuria even when very marked hyperglycemia is present, up to 36 per cent. Hyperglycemia occurred in one of McKay's cases without glycosuria.

Evidence is also given by McCay to show that excessive carbohydrate diet, besides tending to decrease the oxidizing power of the tissues in a direct manner, acts also indirectly by lessening the secretion of the hydrochloric acid of the gastric juice. This leads to fermentative dyspepsia, gastrointestinal catarrh and probably pancreatitis. Whether it be a functional derangement or an atrophy following on chronic inflammatory changes, the pancreatic activity becomes depressed, and, accepting the dextrose ambocceptor theory, the oxidizing power of the tissues becomes lowered. The potential glycosuric in this way quickly comes under the influence of the ill effects of carbohydrate overfeeding, and hyperglycemia and glysuria are rapidly established.

Pathogenesis of Deficiency Disease.—The experimental studies made by McCarrison showed that the morbid state which results in pigeons from deprivation of accessory food factors of the "B" class resembles closely that resulting from complete vitaminic starvation, but is much less often associated with edema. There appears to exist in unmilled rice, as well as in butter or orisons, or both, some factor which tends to prevent the onset of edema. Two food factors appear to be concerned in the production of avian beriberi: (a) the so-called antineuritis factor, and (b) the antiedema factor. The brain, the suprarenals and the pituitary gland are very sensitive to vitaminic influence in the food.

Rapid Hemolytic Serum Production.—By the use of graded strengths of erythrocyte suspension, from 5 to 30 per cent., a saving in the mortality of rabbits used for the production of hemolytic serum by intravenous injection is effected over other methods in which higher concentrations are used. The use of these concentrations in the method described by Iyengar gives a resulting serum of titer from 1:3,000 up to 1:7,000, which were higher titers than were obtained by other methods used. The titers obtainable with different antigens varied markedly. Thus sheep erythrocytes gave much higher titers than goat erythrocytes. The injection of human erythrocytes likewise did not give rise to so potent a serum as the injection of sheep erythrocytes.

Mycotic Affections of Throat in Tropics.—There is a mycotic affection of the throat seen in the tropics due to an *andromyces*. It is described in detail by Acton. This endomycosis differs from the albus in growth, culture mediums required and its effect on the various sugars. Acton has, therefore, provisionally named it "tropicalis." The disease can be reproduced by smearing the culture on the back of the throat. The fungus causes a pharyngitis and in debilitated individuals may extend to the bronchi and set up a fatal bronchopneumonia. It may also infect old tuberculous and bronchiectatic cavities. A 2 per cent. solution of liquor formaldehydi swabbed over the back of the throat will cure the pharyngitis in twenty-four hours.

Theory of Invasion by Infective Agents.—The considerations regarding the formation of antibodies are summed up by McKendrick as follows: The introduction of organisms (or their products) into the body system causes an acceleration in the rate of production of antibodies. It is reasonable to assume that the degree of response is proportional to the logarithm of the stimulus and to the tissue reactivity. The stimulating power of an organism (or its products) probably depends on its degree of saturation (sensitization). These are the hypotheses whose complex forms the theory which McKendrick proposes to adopt. Any disturbance of this relationship, a retardation or acceleration of one sort or another leads to various clinical pictures. For full details the original article should be consulted. A system of classification of diseases due to organismal invasion on the basis of the balance between the protective agencies of the host, on the one hand, and influences acting in a contrary manner on the other, has emerged. This system expresses itself in graded variations in the character of the course and termination of the disease. The main clinical types of disease fall thus into a broken series. Pneumonia, with its critical recovery, stands at the one extreme where protective efforts are in excess. Malta fever, with its succession of relapses, lies very near to the neutral point

where the balance is exact. Passing through diseases of the typhoid group, there is at the other extreme the chronic infection, in which protective efforts are dissipated and wasted. Finally, from a consideration of curves of temperature a method has emerged which McKendrick says may prove to be of considerable value in the prognosis of diseases in general. He is convinced that his mathematical equations, arrived at from however imperfect assumptions, appear to be sufficient to account for the more striking manifestations of organismal infections and to be worthy of acceptance as a working hypothesis.

Bacillus of Gaertner Paratyphoid Group.—A series of inagglutinable organisms culturally and morphologically indistinguishable from paratyphoid were isolated from the blood stream by MacAdam in Bagdad between July and December, 1918, and similar findings have been recorded in a number of cases in other areas of Mesopotamia. The several strains of the organism all have the cultural and morphologic characters of the Gaertner paratyphoid group organisms. It is most closely related to *Bacillus paratyphosus* B and it does not appear to belong to the *B. acetycke* type. Up to the present the organism has been obtained from nine cases, from seven of which it was isolated during routine blood culture investigation of "P. U. O's." In the remaining two cases it was isolated at necropsy from the lungs and spleen, no blood culture having been made during life. The organism has so far not been isolated from the urine or stools in spite of numerous examinations, but at one of the necropsies it was obtained in pure culture from the bile. All the strains give similar microscopic appearances—an actively motile, short, stout gram-negative bacillus or coccobacillus, with some tendency to pleomorphic formation. The growth on agar is less transparent and only in appearance than the usual paratyphoid cultures, and is usually more profuse. There is no liquefaction of gelatin. On MacConkey's medium the colonies are indistinguishable from the paratyphoids. Biochemically the organism produces acid and gas in mannite, glucose, dulcitol, maltose, galactose and arabinose, no change occurring in lactose, saccharose and inulin. Litmus milk becomes at first slightly acid, changing to alkalinity on the fifth, sixth or seventh day; there is no production of indol. On isolation all the strains were inagglutinable even in low dilutions of the high titer serum for *B. typhosus*, *B. paratyphosus* A, *B. paratyphosus* B and *B. enteritidis* (Gaertner). After eight subcultures in broth spread over a fortnight, all the strains had become agglutinable to *B. paratyphosus* B serum in dilutions of 200 and 250; while in the case of four of the strains, each of which was subcultured on thirty occasions, agglutination was obtained in considerably higher serum solutions. Specific serum for three of the strains have been obtained by the immunization of rabbits, a titer of from 6,000 to 10,000 being reached without any difficulty. Of three patients suffering from the infection who died, two were clinically regarded as having lobar pneumonia. At necropsy the same coccobacillus was isolated from the lungs and spleen and in one instance from the gallbladder also. Respiratory symptoms were a prominent feature of most of the cases, while

the symptomatology and course of the fever were usually not suggestive of an enteric group infection. The real identity of the organism is so far undecided.

Commotional Factor in Etiology of Shell Shock.—Experiments were made by Carver on fish, rats and mice, using various kinds of explosives in varying quantities and at varying distances, to determine the existence of commotional and emotional syndromes. Carver tried to outline a picture of the early syndrome which distinguishes the more severe cases of commotional shock, but the symptoms in slighter cases become almost inextricably blended with others which appear identical with those resulting from emotional shock. Hence, Carver concludes that while one may at the two extremes deduce with each the nature of the primary pathogenic factor from a study of the syndrome exhibited, this becomes increasingly difficult as one approaches the intermediate members of the series, and one's judgment is largely determined by the aspect from which one approaches the problem.

Colectomy.—Taylor is an advocate of colectomy in appropriate cases. He has performed the operation six times with excellent results. The rapid improvement in general health was striking; there was no trouble with diarrhea, the bowels only moving about twice a day. Attempts to relieve patients by partial operations were not very successful.

Aneurysm of Heart Without Symptoms.—Wilson's patient was 60 years of age. She had never been ill or an invalid. She died suddenly while attempting to vomit after having had what was believed to be a "stomach" attack for about twelve hours. At the necropsy attention was immediately centered on the bulging pericardium. On puncturing it blood gushed out, and the sac was found to be full of blood, partly liquid and partly clotted. The heart itself was small and the walls rather thin and pale. On the surface of the left ventricle, about an inch above the apex, was a dark circular patch rather smaller than a shilling with a small rent in the center. On section, the patch proved to be a collapsed aneurysmal dilatation; the central portion, where the rupture had taken place, was hardly thicker than brown paper. In other respects the heart appeared normal.

Duplication in Human Spermatozoa.—Tattersall's patient was a man, 25 years of age, suffering from spermatorrhoea. The greater number of spermatozoa were normal, but in a few instances one head was furnished with two distinct tails. The tails were quite separate and distinct as far forward as the posterior end of the middle part, with which they joined. The proportion of two tailed to normal sperms was about 1:750. A second type of abnormality was also observed. One or two spermatozoa were furnished with two heads and one tail. No abnormality was found in the sexual history of the man's family. There has not been a marked preponderance of one sex among the children born, nor has there been an instance of twins or abnormal children for two generations back.

Concussion and So-Called Shell Shock Headache.—The authors suggest that the explanation of the long continued and intractable headache coming on after the concussion caused by a high explosive shell is due to the perpetuation by autosuggestion of a headache which is at first organic in

origin and a genuine result of concussion. Being produced by suggestion and cured by psychotherapy, it can be correctly called hysterical. While not every case of prolonged headache following concussion is of this nature, the authors have seen several cases in which psychotherapy was extremely effective after all other methods had failed. It is further suggested that the chronic headache which follows concussion in civil life is probably often of similarly hysterical origin.

Hysterical Trismus and Other Neuroses of Jaw.—Cases are cited by Wilkinson to show that heterosuggestion plays a prominent part in the development of hysterical trismus.

Asthma in Children. J. Condy.—p. 372.

Inherited Syphilis and Points of Lesser Resistance.—Hutinel explains in detail how the taint of syphilis inherited possibly through several generations may render certain organs, glands, bones or other tissues points of lesser resistance. Their development may not be quite finished, and any intercurrent infection localizes by preference at these points of lesser resistance and may persist interminably. Chorea, for example, is exceptionally frequent among children with inherited syphilis. This taint also throws light on the chronic course of nephritis, and as a factor in rachitis it is far from negligible. By thus enlarging the field of syphilis, he offers a prospect of more effectual therapeutics in all these abnormal conditions. Treatment for the inherited syphilis may eliminate this factor more or less completely. He reports encouraging results in abnormal or severe rachitis, anemias, interminable nephritis, cirrhosis of the liver, etc., and warns that the progenitor responsible for the taint may be more than one generation back.

Syphilitic Ulceration of the Umbilicus.—The ulceration at the umbilicus of the month-old babe was unmistakably syphilitic, and seemed to be the only appreciable manifestation of the inherited disease.

Gas Cysts in Abdomen.—Tuffier and Letulle report a case of fatal stenosis of the small intestine from the effects of thousands of minute gas cysts in the abdomen. In a second case all the abdominal symptoms subsided after gastroenterostomy. They have found sixty-four analogous cases of encysted pneumatosis on record.

Bone as a Food.—Bernier refers to veal or chicken spongiosa bone cooked in a soup and eaten. Every one, he

says, is surprised to find how it can be chewed and how palatable it is. The teeth profit by the mineral salts, and the whole system gains, especially when tuberculosis impends.

Restriction to Milk in Diabetes.—Le Noir thinks that anti-diabetic diet is liable in time to have untoward effects in persons predisposed to arteriosclerosis, gout, etc., and hence that an occasional change to a milk diet is beneficial. Consequently he orders for an occasional five-day period restriction to 2 or 3 liters of milk taken at brief intervals during the day. In 80 per cent of his seventeen cases marked improvement was realized. In four of the cases the sugar disappeared from the urine after the first course of milk; in nine others it dropped by two thirds or a half after each course.

- *Operative Treatment of Severe Hematemesis. M. Cazin.—p. 53.

Forceps in Small Intestine for Twelve Years.—The woman of 63 had had more or less digestive disturbance for a number of years, and Mercadé was operating on account of aggravation of the condition when he discovered casually in the small intestine a hemostatic forceps. A herniotomy had been done twelve years before, and before this a gynecologic operation. The forceps had not been able to pass the ileocecal valve but it had not caused any very serious disturbance during all these years. The intestinal juices had corroded off one blade. The appendix was 22 cm. long, and it was not until after this had been removed that he felt the point of the forceps in the bowel.

The Campaign Against Tuberculosis.—Armaingaud recalls that in 1882 he pointed out the magnificent results obtained in combating tuberculosis by the thirty years of work at the Bercé seashore hospital and urged the foundation of little Bercés all along the sea coast, so that in a few years there were seventeen seashore sanatoriums in France. In 1891 he founded the Ligue française contre la tuberculose and in 1899 he founded at Paris twenty courses of lectures on *hygiène antituberculeuse*, one in each ward, each course consisting of eight lessons. It was not until 1894 that Germany roused to undertake similar work. He adds that the German sanatorium statistics include large numbers of persons who had merely nontuberculous bronchitis, etc. He ascertained this in 1902 when he visited a number of German sanatoriums. He adds further that the official statistics for the tuberculosis mortality in Prussia during the seven years, 1896-1892 just before the sanatoriums had been founded—showed a decline of 28 per cent, while during the following seven years the decline was only 23 per cent. He presents evidence further to the effect that an important element in the sanatorium propaganda in Germany was a scheme to sell sanatorium supplies, furniture and equipment generally to other countries.

Operative Treatment for Recurring Hematemesis. Cazin reports the case of a man of 51 who had had three severe hemorrhages from the stomach during the night after a nervous shock. Nothing but a minute erosion was found near the cardia and a group of clots elsewhere. Each point was sutured together with an over and over catgut suture through the mucosa, and smooth recovery followed. In three other cases the hematemesis came on as the first sign of trouble from the stomach. In one, five minute, bleeding ulcerations were found grouped together on an area about 5 by 13 mm. He arrested the bleeding in the same way by a transverse catgut suture, suturing the stomach with silk. In another case a severe hematemesis recurred three times with a few days' interval. A bleeding point was found in a small lynch, a Brunnerian adenoma, 4 or 5 mm. in diameter, which he resected. Recovery was incomplete and the young man served afterward all through the war. The outcome has been equally satisfactory in the other cases after these simple interventions. It confirms Dieulafoy's statement that with recurring

hematemesis, with menacing symptoms, an operation must be done at once as such interventions are practically harmless.

- *Section of Kidney Pelvis. G. Marion.—p. 43.

Improved Technic for Nephrostomy.—When the kidney has to be long drained or the urine permanently diverted from it, Marion works a Tripier dilator into the kidney down into

Fig. 1.—The drain is slipped through the dilator into the pelvis and held there as the dilator is withdrawn.

Fig. 2.—The right-angled drain with disk for holding the drain firmly in place.

Fig. 3.—The drain in place. A rubber bag fits over the lower end for the urinal.

the kidney pelvis. The 1 cm. incision for the purpose is made at the lower third of the external aspect of the kidney, and the dilator is pushed in until it can be felt in the well exposed kidney pelvis, freed from adipose tissue. The branches are then spread and a right-angled drain is pushed down through it into the kidney pelvis and fastened with a catgut stitch to the capsule. The whole procedure is complete in a few seconds (*je ne dis minutes*), and works perfectly. One of his patients has been wearing a drain of this kind for eight years, leading an otherwise normal life, and no one suspects that he wears a urinal as the fact that the drain reaches into the pelvis prevents seeping of urine. Another patient has worn the drain twelve years. He is not incommoded by his drain. He rises out the pelvis every morning and sometimes changes the drain himself. Both of these men had had the other kidney removed long before

and calculi kept forming in the remaining kidney until it was drained. If the nephrostomy is done to isolate the kidney from a tuberculous bladder, the ureter should be severed. Nephrostomy without drainage is absolutely bad, he declares.

Correction of Error with Catheterization of Ureters.—Pirondini gives some mathematical formulas for this purpose.

Excision of Tuberculous Epididymis and Vas Deferens.—In Chabrier's case the tuberculous right testicle and epididymis had been resected seven years before he excised the epididymis and the vas deferens on the other side, up into the iliac portion of the canal. There has been no recurrence since.

Escape of Kidney Pedicle.—When the ligature or clamp slips and the pedicle slips back while the blood pours from the vessels in it, Marion protests against trying to seize it with forceps. All that is necessary is to tampon hard, pile up the compresses, and then wait four or five minutes. When the tampon is then removed either there is not a drop of blood or merely a slight jet, easily controlled.

Lyon Médical

June, 1919, 128, No. 6

Recent Legislation on Poisonous Substances. R. Lecomte and R. Bonlied.—p. 273.

*Dysentery and Edema. J. F. Martin and A. Delord.—p. 281. Conc'n.

*Pathogenesis of Fever. Widmann.—p. 286. Conc'n.

Dysentery and Edema.—Martin and Delord report five cases of dysentery with ascites, effusions in joints or edema in the legs, all without any signs of nephritis. All but one young man were about 40 years old, and the edema appeared during convalescence. It lasted from one to ten weeks. Only four other recent cases have been published, but older writers mentioned dropsy as comparatively common with dysentery. In the five cases described here, the edema was accompanied by polyuria and the urine contained large amounts of chlorids, from 23 to 36 gm. instead of the normal average of 10 or 12 gm. The salt content of the blood was low, from 5.38 to 5.90 per thousand, instead of the normal 6.75.

Pathogenesis of Fever.—Widmann here presents further evidence to sustain his conception of the origin of fever. It was recently described in these columns, July 19, p. 231.

*Congenital Debility and Atrophy. Lesage and Kouriamsky. p. 193.

*Treatment of Habitual Vomiting. A. B. Marfan.—p. 205.

*Browning the Infant's Food. M. Forest.—p. 217.

Congenital Debility and Atrophy.—Lesage and Kouriamsky found that congenital atrophy was due to inherited syphilis in 25 to 35 per cent. of the cases; the Wassermann reaction was positive in this group. In about 50 per cent. there was no Wassermann reaction and an inherited taint from tuberculous or physical exhaustion of the family or acquired infection was responsible for the atrophy. The atrophy in these two groups is accompanied with transient muscular spasms, but alcoholism is the inherited causal factor with tenacious and persisting spastic atrophy, with negative Wassermann. When syphilis is a factor they give neo-arsphenamin every eighth day, only very slowly increasing the dose from 0.0025 to a maximum of 0.01 gm. After six or seven injections, they suspend it for two months and commence a new series. These small doses can be begun at once after birth, but they should be stopped in case of fever. They reiterate that this technic is the best treatment for latent syphilis in young infants. When there are visible lesions the promptness with which they subside confirms the efficacy of this treatment. The vein at the elbow usually served best, exceptionally, they made the injection in the superior longitudinal sinus. The infant on the day of the injection is fed only with sweetened boiled water. Mercury has not proved satisfactory for treatment of young infants, they say. *Il expose à bien des mécomptes.* The same can be said of neo-arsphenamin when given in such large doses as 0.01 gm. per kilogram, such as Blechmann advocates.

Habitual Vomiting in Infants.—Marfan remarks that when syphilis is a factor in habitual vomiting the infants seem to

tolerate mercury lactate by the mouth better than other preparations of mercury. In any event, the child must be fed in spite of his vomiting. Complete and protracted deprivation of food may aggravate the tendency to vomit. The essential point in treatment is to get the child fed, rather than to check the vomiting. If breast milk is absolutely unattainable, asses' milk is the next choice, and next to this, skimmed cow's milk. It is the latter in milk that causes the most disturbance. These infants bear sugar well, and addition of 10 per cent. sugar to skim milk adds materially to its nourishing power. Kéfir and buttermilk may answer, but generally they are too acid. He uses them only when diluted with one third water and one third (official) lime water. If the infant is 3 months old, he adds a thin gruel with or without maltose; over 6 months a little thicker gruel or *bouillon de légumes*, with increasing proportions of milk. The stomach does not seem to be able to expel these semi-fluid substances so readily.

When the condition is serious, the infant tolerates better very small feedings at short intervals. He begins with a 2 months babe with restriction to one or two teaspoonfuls of ice water every half hour. Half a day of this rests the stomach completely. Then he begins to feed with a spoon breast milk or whatever food is to be used, not allowing the child to suck as this is liable to arouse the vomiting reflex. All the food should be ice cold, and he gives a teaspoonful every fifteen minutes. If during six hours any of this is retained, he gives two and then three teaspoonfuls every half hour for six hours, and the last quarter of the day gives four or five teaspoonfuls and lets the child sleep unmolested for six or seven hours. The amounts are gradually increased, the intervals lengthened and breast feeding is resumed according to the child's tolerance. By following this plan, the child may still vomit occasionally but enough of the food is retained so that the weight shows gains.

If the vomiting persists in spite of this care, he feeds the child with a medicine dropper, giving the food by drops in the child's mouth every three or four minutes. A thickish rice gruel may be used at one feeding if the child is over 5 months old. He describes other means to vary the feedings, and outlines Hess' method of diadrenal feeding, mentioning also Fredet's success in feeding breast milk by the rectum. The underlying nervous excitability must not be neglected, and the bottle should be held almost vertically, instead of horizontal, to prevent swallowing of air. After feeding, the infant's trunk should be held vertical a few minutes to favor expulsion of some of the air swallowed. Hot enemata (40 or 45 C., 104-113 F.) help in combating vomiting, from 120 gm. at 3 months to 200 gm. at 6 months twice a day from the first and later once in two days. Bismuth may be useful, given before feeding to form a protective coating in the stomach, a teaspoonful of a mixture of 2 gm. bismuth subnitrate in 45 c.c. each gum mixture and syrup of poppies. Or 0.25 gm. bismuth subnitrate may be added to the bottle. Hot compresses (55 C., 131 F.) applied to the stomach and abdomen, renewed every hour for five or six hours, may be indicated in the graver cases. Twice a day the child can be put in a hot bath (38 C., 100.4 F.) for ten minutes. Still another measure, if all else fails, is a kind of gentle massage of the abdomen twice a day for five minutes, the hand greased with camphorated oil of chamomile. In these extreme cases, relatives are called for, and tincture of belladonna is better than opium preparations. The latter do not give good results. He adds to the belladonna some bromid, which reinforces its action, and some sodium bicarbonate as hyperacidity is frequent in these extreme cases and as the bicarbonate has also an anesthetic action. He describes further the technic for lavage of the stomach; this sometimes aids but he warns that in certain conditions it may bring on convulsions.

Browned Flour and Milk.—Forest reports four cases in which *lait au four* seemed to offer peculiar advantages in feeding the infant. In five other infants it was a failure. It is made by heating 7 per cent. butter and 7 per cent. flour over a gentle flame and diluting with water containing 5 per cent. sugar. Then a third or two fifths of boiled milk is added. Heating the butter seems to dispel the volatile fat

acids which are regarded as injurious for the digestive tract. The four infants that thrived on it not only gained in weight but the stools were more numerous and bulkier than with any other method of artificial feeding. There is no starch in the stools and the increased bulk is the result of the stimulation of the digestive secretions by the "flavored milk." Hence its special field is for infants with hypotrophy and atrophy but no gastro-enteritis.

Paris Médical

July 3, 1919, 9, No. 27

- *Angina Pectoris and Syphilis. O. Josse—p. 1.
- *Instability of Heart and Temperature. C. Laubry—p. 4.
- *Influenza Phlebitis. P. Lereboullet and J. Hutinel—p. 7.
- *Cardiac Murmurs. C. Esmein—p. 9.

- *Hereditary Suprarenal Convulsions. C. Aubertin—p. 18.
- *The Sign of the Drooping Apex. J. Jomier—p. 20.
- *The Arterial Tension in Influenza. L. Tixeront—p. 22.

Angina Pectoris and Syphilis.—Josse has been applying the Wassermann test to persons who have had true angina pectoris, but he obtained a positive response only in 33 per cent. These negative findings were contradicted, however, by the success of treatment as for syphilis. There were no further attacks after specific treatment in 90 per cent. of his nine cases. In a few there was slight return of the pains later, but they subsided anew on resumption of treatment. Arspenamin does not answer; it may bring on serious disturbances with aortic lesions. He obtained the best results with mercurial treatment in minute doses, alternate days, a series of fifteen. This is a vigorous and yet cautious treatment. Josse declares that angina pectoris seems thus to be an almost certain sign of syphilis even in the entire absence of other stigmata of inherited or acquired syphilis. Several convincing cases are reported.

Unstable Heart and Temperature.—Laubry has found that when the heart rhythm keeps normal but grows faster or slower under ordinary stimuli, the temperature fluctuates likewise. Some men presented at times a temperature 1 or 2 degrees higher late in the day than in the morning. Prolonged repose brings it down but not quite to normal. In others there was subnormal temperature in the morning, with a rise of 2 degrees by evening, sometimes. Some of the subjects with this *instabilité thermique* have been under observation for over a year but nothing pathologic to explain this instability has been encountered at any time beyond the unstable balance in the nervous and circulatory system. It may modify decidedly the temperature curve during an intercurrent infectious disease.

Phlebitis from Influenza.—Lereboullet and Hutinel report ten cases from their experience during the recent pandemic in which influenza was followed by phlebitis. It was bilateral in some, and the course was mild.

Interpretation of Heart Murmurs.—Esmein regards the French method of examination for heart murmurs as far superior to the British for various reasons which he explains. It consists in thorough auscultation supplemented by compression of the eyeball. This latter reinforces organic murmurs and weakens or abolishes the inorganic. Radioscopy supplies further evidence when needed. The British accept as organic every diastolic murmur, while the systolic is assumed to have no significance, but this is not accurate.

Dizziness with Insufficiency of the Aorta.—Heitz explains that the dizziness is not actual vertigo, but merely a sensation of emptiness or heaviness in the head which compels a person to sit down to avoid falling. It is evidently due to some disturbance in the circulation in the brain.

Convulsions with High Blood Pressure Without Nephritis.—Aubertin describes the case of a woman of 40 with high blood pressure, hypertrophy of the left ventricle, hyperplasia of the suprarenals, and convulsions, and yet the kidneys seemed to be practically normal. There was aortic insufficiency in this case, but in a second similar case the only assumption seems to be a primary hypertension.

The Lagging Apex Beat.—Jomier comments on the frequent existence of aortic disease when the apex beats sluggishly.

Progrès Médical, Paris

June 14, 1919, 34, No. 24

- *Laboratory Findings Compared with Clinical Course in Tuberculosis Suspects. C. Roubi—p. 229.
- *Sjögren's Treatment of Organic Nervous Disease. M. de Lépinay—p. 235.

Tuberculosis Suspects.—Roubi reviews his experience with his last series of 1,000 tuberculosis suspects. With an actual tuberculous lesion at the apex, the clinical and the roentgen findings harmonized in 90 per cent. but the roentgen rays always revealed more extensive lesions than would be surmised otherwise. In some of the others, bronchitis masked the pulmonary lesion but there were four men with no moist râles, no symptoms of condensation and no crepitation after coughing, and repeated examination failed to reveal any physical signs of a tuberculous lesion, but the roentgen rays showed extensive infiltration and tubercle bacilli were found in the sputum. Atypical cases of this kind formed 4.5 per cent. of the men with positive sputum, and they impose the necessity for raying all suspects even when daily percussion and auscultation give negative findings. In five other cases roentgenoscopy showed persistently normal findings, but tubercle bacilli were found in the sputum in some of them after expectoration had been induced with iodid. Rist declares that when nothing abnormal can be seen on the screen or roentgenogram, the lung is unquestionably normal. Roubi adds that in these cases he had to content himself with roentgenoscopy alone; it is possible that in an instantaneous roentgenogram something abnormal might have been detected. In 16 per cent. of the cases with positive sputum, both clinical and radiologic findings were so slight as to be only dubiously perceptible. He discusses further the cases with lesions at the base or middle of the lung, and the 307 with chronic bronchitis or permanent impediment to breathing through the nose which had caused the mistaken diagnosis of tuberculosis. This group included further seventeen cases with syphilitic or malignant lesions in the lung or an abscess or interlobar empyema, or else the men (201 cases) were merely narrow chested and suffering from exhaustion, dyspepsia or heart disease. Thus in over 50 per cent. of the 1,000 men the suspicion of tuberculosis proved to be unfounded.

- Intestinal Obstruction from Ascariids. Id.—p. 176.
- Contagion from Supposed Haled Chancres. P. Nathel—p. 181.

Feeding Infants through a Catheter.—Kotzareff gives an illustration of the funnel and catheter with interposed tube, Murphy cock and glass cannula, which he uses to feed infants when conditions in nose, mouth or throat prevent normal feeding. He takes about ten or fifteen minutes to feed a very young infant in this way, imitating the drop method of proctoclysis.

Ascariids Induce Ileus.—In Kotzareff's two cases the women of 40 and 60 had never shown any symptoms of ileus or helminthiasis. Acute ileus compelled an operation, and it disclosed that in both there had been partial occlusion from membranous bands. This occlusion had suddenly become complete from obstruction by ascariids.

- Deliriums in the Brain According to Monakow. P. Ladame—p. 32.

Disorientation in Space After Wound of Frontal Lobe.—Marie and Béhague remark that the war wounds have thrown much light on the functions of the frontal lobe. Deep lesions in particular of the prefrontal region seem to have entailed

disturbance in the sense of space in the absence of any objective sign of injury of the nervous or vestibular system. There is no or very slight tendency to headache, dizziness or temporary dimness of vision. The disturbance in orientation is solely in the sense of direction while the idea of time seems to be normal. The various forms of this disturbance are discussed with a few illustrative cases, the details of twelve being tabulated for comparison.

Herpes Zoster of the Face.—The propagation of the herpes to the sympathetic system, ganglions and connected fibrils is described as studied on various cases before and during the war.

Inherited and Familial Exophthalmic Goiter.—Souques and Lermoyez relate that in the family described there have been seven cases of exophthalmic goiter among the sixteen members of the family in three generations. They give illustrations of the four members they have personally examined. The tendency seemed to be transmitted by the males. There were no signs of inherited syphilis; the trouble must be some inherited predisposition rendering the thyroid peculiarly susceptible to diverse infections and intoxications. They list the few similar familial cases on record. In one, dating from 1884, eleven of the sixteen members of the family had developed exophthalmic goiter.

Correspondenz-Blatt für Schweizer Aerzte, Basel

July 10, 1919. 49, p. 28

*Obstetric Examination. E. Jegge, p. 1033.
Influenza and its Mental Complications. C. Ludame, p. 1050

Obstetric Examination.—Jegge remarks that notwithstanding rubber gloves and all precautions, the morbidity of the puerperium still ranges from 5 to 20 per cent. He ascribes this to the woman's own germs, saying that it is absolutely impossible to ensure asepsis of the vagina. He tabulates the findings with 500 parturients examined internally with every precaution and 500 in which no attempt at internal examination was made. These figures include only spontaneous deliveries and no cases of laceration of the perineum. The morbidity was much higher in the internal group and also in the primiparae in both groups. His figures and experiences converted him to the necessity for refraining from internal examination, and he says that he has accomplished very nearly as much without it. He soon learned to tell by palpation from without whether the head was presenting or not, and how far down it had got and its position. With the hand on the perineum of the woman lying on her side, the palm on the lowest segment of the sacrum, the finger tips between the coccyx and anus, slowly pressing inward and upward during an interval between labor contractions, and then giving an abrupt rapid pressure, the hard head can be palpated if it is in the pelvic cavity or pelvic outlet. If the head with its longest diameter has not yet entered the small pelvis, then the findings with this back-of-the-perineum maneuver are negative. If a muscle interferes with it, telling the patient to strain gets this out of the way. This maneuver is particularly useful when palpation from the front is impossible on account of obesity or painfulness. It gave the desired information in nearly 95 per cent. of his cases.

The degree of dilation of the os can be ascertained by way of the rectum almost as well as through the vagina. This is not painful and occasions at the most an unpleasant sensation of pressure. It has a special advantage if cesarean section becomes necessary, but it does not inform in regard to the diameter of the external os. This can be ascertained very readily by palpation of the contraction ring, the wall-like ridge where the thick nonelastic wall of the body of the uterus joins the elastic zone of the cervix. This passive, thin, lower part of the uterus forms an elastic tube, as it were. As this tube stretches, the circular ridge at its upper limit is pushed up, and this pushing up of the contraction ring can be followed with the palpating hand. The height of the ring is thus an index of the increasing diameter of the os. When the os is fully dilated, the distance from the external os to the contraction ring is 10 or 11 cm. This brings 8 or 9 cm. of the distance above the upper margin of the symphysis; this is about equal to four fingerbreadths. At three fingerbreadths the os is as wide as the palm; at four finger-

breadths, the os is fully dilated. If the contraction ring cannot be palpated at all, the os can be assumed to be not wider than a 5 franc piece. Jegge's experiences with this method confirmed its instructiveness and reliability in 91 per cent. of the 100 cases tested. It failed in 4 per cent.; in 5 per cent. various causes conspired to prevent a correct result. By these different means of external examination it is possible to dispense with vaginal examination in very nearly every case. In any event they should precede the latter except possibly when indications call for rapid termination of delivery or anomalies require special measures or the findings with external examination are too vague. In conclusion he reiterates that physicians and midwives fail to realize the responsibility they incur with internal examination, especially with contracted pelvis and placenta praevia which may demand cesarean section. It is never indifferent, and is often directly dangerous even with every possible precaution by experts.

*The Initial Phase of Scurvy. O. Cozzolino, p. 407.
*Nodose Erythema. C. Pestalozza, p. 435.

Preleukemic States in Children.—Martelli applies this term to a condition in which the blood is of the leukemic type in children with some inherited taint and constitutional predisposition to anomalies in the thymus and lymphatic system. He has long made a special study of blood diseases, and has come to the conclusion that leukemia, lymphosarcoma, etc., are preagonal states; the organism exhausted by its cytotoxic struggle has yielded to the action of the pathogenic causes that have been undermining it. By keeping oversight of changes in the blood, we can see when this cytotoxic struggle is going on, and when collapse is impending, so that by prompt measures we may be able to ward it off, combating the underlying syphilis, tuberculosis, malaria or sepsis. He describes seven cases in detail with the necropsy findings in some, and declares that this preleukemic state is peculiarly liable to develop early in life. The metaplasia of the blood-producing tissues may be the unsuspected fatal factor in many cases of anemia, enteritis, hemorrhagic diathesis, malaria, syphilis, tuberculosis, etc. In forty-five cases of leukemia he found tuberculosis in thirteen; syphilis in seven; malaria in five, streptococcus or staphylococcus sepsis in four each, and various bacterial associations in ten. By vigorously combating the primary disease, the tendency to the preleukemia may be arrested, and he suggests that it might be possible to arrest the tendency to metaplasia of the blood-producing organs by roentgen treatment as for established leukemia. He has no facilities for this himself, but hopes that others will give it a trial. There is no doubt that the preleukemia stage, which reveals the toxic metaplastic irritation of the blood-producing organs, can be checked and conquered if the physician examines the blood and gives the proper treatment when he notes intense pallor, unjustified hemorrhages, enlargement of glands and spleen without any apparent infection to explain them.

Scurvy in Infants.—Cozzolino refers to the initial phase, the vague abortive type in particular which occurs in infants the same as in adults, and often escapes detection unless the gums are examined as a routine measure. In the eight cases described of this initial type, the infants were from 12 to 26 months old, and all but two were boys. He compares the literature on the subject from various countries. In forty-seven out of ninety cases published from Parma, the parents were poor, while in other countries the well-to-do classes seem predominantly affected.

Erythema Nodosa.—Pestalozza calls attention to the fact that tuberculosis was beyond question in the seven cases described of erythema nodosa in children.

*Tumor in Esophagus Simulating Anomalous A. Litvak, p. 518.
*The Kidney as an Organ for Hemodialysis. T. Solovitz, p. 523.
*Anticoagulation in Phlebotomy with Elixon. F. Molloy, p. 527.
*Intestinal Diverticula Related to Surgery. J. Anselmi, p. 527.

Tumor in Esophagus.—Litvak remarks that a tumor may be long developing in the esophagus without causing the slightest symptoms. Then, when it reaches a certain size or a larger lump of food is passing it, serious pain and difficulty in swallowing develop suddenly. The pain and dysphagia may then temporarily subside if the tumor softens, or they may progress. The pains may deceptively resemble those with aneurysm of the aorta. He calls attention in particular to pain in the back and left side of the neck, its tenacity and intensity and the exacerbation when the neck is stretched, while the pain is relieved by bending the neck. The trachea may be pushed aside with either tumor or aneurysm, and adhesion to the aorta may permit transmission of the aortic pulse to the trachea, as may occur with aneurysm. In a case reported the tumor protruded both into the lumen and outside, and had induced recurrent paralysis.

The Kidney and Hemolysis.—In this preliminary note, Silvestri reports further research which seems to confirm his previous statements in regard to the destructive action on kidney tissue and also on the blood of pathologic kidney tissue injected into the peritoneum of animals. Scraps of other organs injected in the same way have a similar destructive action on kidney tissue but not on the blood; the hemolytic action seemed to be peculiar to kidney tissue in such experiments. He has had under supervision for years several cases of paroxysmal hemoglobinuria, and in three he has never been able to detect hemoglobinemia but each in this group has chronically pathologic kidneys with a history of nephritis from five to nine years before.

April, 1919, 17, No. 4

*Latent Tuberculosis in Nurslings. L. M. Spolverini.—p. 160.
*Infant Feeding in Italian Manual, 1882. A. Spallacci.—p. 187.

Latent Tuberculosis in Infants.—Spolverini has applied tuberculin skin tests to 900 supposedly non-tuberculous children under 1 year old, and obtained a positive response in 63. This is 7 per cent. in all, but only in 0.80 per cent. of the 8 infants 3 or 4 months old; 2.44 per cent. of the 22 from 4 to 6 months old, and 3.66 per cent. of the 33 from 6 to 12 months old. The predisposing causes in the infants and in the parents and environment are tabulated, with the pathologic findings in the infants. Radioscopy showed that the glands at the right hilum were affected more often than the left; those at the left hilum do not show unless they are of considerable size, being concealed by other shadows. These glandular lesions could be detected only by raying. From the clinical point of view the tracheobronchial glands are the first manifest localization of the disease. His table emphasizes that familial contagion is the most dangerous factor, and that in the cities search should be made for infants born into an infected environment and they should be taken away into the country, with close medical surveillance.

Early Pediatrics in Italy.—Spallacci quotes freely from a work published by Mercuriale in 1552, with the title "Nemotelasms," dealing with the feeding and training of infants and young children. It shows, he adds, that pediatrics in Italy was born from enlightened common sense.

*Anomalous Form of Tuberculous Meningitis. C. Jorras.—p. 13.
*Operative Treatment of Spastic Paralysis. M. B. Ansart.—p. 92.
*Differential Diagnosis of Tumor in Mediastinum. F. Suárez.—p. 48.
*Clinical Forms of Influenza. R. Grau y San Martín.—p. 73.

Anomalous Form of Tuberculous Meningitis.—Jorras describes the unusual type of inflammation, latent, protracted, and the second stage with symptoms suggesting an ordinary infectious disease. There may also be anomalous predominance of one or more symptoms and the disease may affect certain regions exclusively and may induce clinical pictures simulating chorea, Little's disease, intoxication and poliomyelitis. The disease may also prove misleading on account of the absence of the usual symptoms.

Operative Treatment of Spastic Paralysis.—Ansart refers to Stoffel's operation which after a brief vogue seems to be now discarded by surgeons in Spain. But he insists that this operation is the preferable intervention with spastic paralysis, basing his statements on four cases in his own experience and on the physiology of nerves (Cajal), as well as on extensive experiments on dogs. His experience and reasoning further teach that an operation on the tendons should supplement the Stoffel operation when the contracture has reached a certain stage.

Epinephrin in Rachitis.—Corominas ascribes to endocrine insufficiency an important share in the production of rachitis, and declares that epinephrin is indicated to whip up the endocrine system.

*Conjunctivitis of the Fornix. J. Santos Fernández.—p. 83.
*Technic for Dacryocystectomy. M. V. Escalano Sabater.—p. 96.

Conjunctivitis of the Culesac.—Santos Fernández gives an illustration to show how infiltration and swelling of the conjunctiva between the tarsal portion and the bulbar portion can be detected by everting the lid. The conjunctivitis then shows as a red and swollen line along the lower edge of the fold made by the everted lid. Pus can accumulate in this culesac and escape local treatment. It has sometimes been mistaken for trachoma. The process in the culesac is not actual inflammation but the infiltration feels like a foreign body, and keeps up an irritation of the nerves that sets up a red-x winking and twitching of the eyelids. This is so characteristic that the conjunctival culesac should always be examined when a tendency to abnormal contraction of the eyelids is noted. The patients have always been boys in his experience. Local treatment is that for any mild conjunctivitis, but as the subjects are usually of the lymphatic constitution, general hygiene is particularly important in such cases, and a change to seashore or mountains. The affection is not contagious, but the subjects are peculiarly susceptible to infection and hence should be guarded with special care against infection of all kinds.

*Chagas' Trypanosomiasis in Venezuela. E. Tejera.—p. 113; Pino Pou.—p. 113.
*Appendicular Dyspepsia. L. Razzetti.—p. 114.
*Perforation of Intestine in Typhoid. A. d'Empaire.—p. 116.

American Trypanosomiasis in Venezuela.—Tejera and Pino Pou each describe a case of Chagas' disease in Venezuela, and report the finding of *Trypanosoma cruzi* in the insects, *Rhodnius prolixus*.

Typhoid Perforation.—D'Empaire relates that the perforation occurred at the ninth day of typhoid in his little daughter of 7. There had been profuse diarrhea during the disease. A large perforation was found in the ileum and a patch nearly seemed on the point of perforating, but as this intestine seemed in good condition otherwise, these two regions were sutured. In this and in three other operative cases the median laparotomy gave ample oversight.

*Roentgen Diagnosis of Gastric Ulcer. A. Inclán.—p. 55.
*Ichthyol Internally in Urticaria. I. Espín.—p. 65.
*Differential Diagnosis of Tumor in Mediastinum. F. Suárez.—p. 68.
*Clinical Forms of Influenza. R. Grau y San Martín.—p. 73.

Ichthyol Internally in Urticaria.—Espín reports six cases in adults and children in which marked improvement followed internal administration of ichthyol. In the first case the colored man had been tormented for nine months with intense itching, only briefly relieved by any measures. The itching was most severe in the palms and soles. It had begun eighteen months before, and of late it had become so intense that the man was unable to sleep. Espín gave him a pill of 0.25 gm. ichthyol and 0.10 gm. magnesium carbonate.

He fell quietly asleep forty-eight hours later, and has had no signs of the urticaria during the year and a half since. In a case of urticaria following the eating of fish, the cure was not complete until ten days after the ichthyol had been begun. Others were cured in one or three days. The dose was reduced for a child of 9 to 0.15 gm. of the ichthyol and 0.05 of the magnesium carbonate. Espin does not attempt to explain the action of the ichthyol in these cases but his success in the otherwise rebellious cases speaks for itself.

Tumor in Mediastinum.—In Suárez' case there had been intermittent periods of difficulty in breathing and in swallowing for nearly four years, and they had been growing more frequent and severe and the dyspnea finally interfered with sleep. The trachea was pushed toward the right and a small tumor could be palpated in the right suprascapular triangle, but the veins and glands in the region seemed normal and the assumption of a benign tumor was confirmed by the successful operation. There was nothing to suggest syphilis or alcoholism. In conclusion Suárez reviews the various sets of symptoms induced by tumors at different points in the mediastinum.

*Histologic Research on the Membranous Labyrinth of the Tadpole. T. Asai—p. 315.
*Distribution of Iodin in Animal Body. K. Fujisawa—p. 389.

The Labyrinth in the Tadpole.—Asai studied both the toad and the frog tadpole, with special research on the physiologic functions of the terminal nerve epithelium of the pars neglecta of the membranous labyrinth. He offers what he thinks is a satisfactory explanation of this function.

Distribution of Iodin in the Body.—Fujisawa reports extensive chemical and experimental research which has apparently established that organs with a tuberculous focus contain more iodine than others. In tuberculous tissue, the iodine forms an organic compound with fat and lipid substance but not with albumin. Organs with a suppurating focus, bacterial or aseptic, also contain more iodine than usual, but the iodine in the pus is in the form of an alkaline iodide and not as an organic compound. Cancer tissue also stores up more iodine than ordinary tissues; sarcoma not so much as carcinoma. The largest proportion is in the softened part. Syphilitic tissue takes up more iodine than other organs, and it forms an organic compound with fat and lipid substance but not with albumin. The iodine in exudates is in the form of an alkali iodide, not forming an organic compound with fat and albumin.

*Dangers of Acetylene Welding. J. P. L. Hubst—p. 1933.
*Underfeeding and Cerebral Lesions. J. K. A. Wertheim Salomonson—p. 1941.
*Underfeeding of Children. M. van der Hoeve—p. 1948.
*Tonsillectomy and "Thymus Death." H. Burger—p. 1951.

Dangers of Acetylene Welding.—Hubst explains that carbon monoxide poisoning was probably responsible for the death the fourth day of the man of 34 who had been welding for half an hour inside a large boiler. Acetylene gas does not contain deadly phosphorus and sulphur gases or nitric acid, and the necropsy findings were negative, including spectroscopic examination of the blood. This does not conflict with the assumption of carbon monoxide poisoning as this gas soon disappears from the blood after it has done its deadly work. Since the man had been given welding work to do he had complained several times of nausea and that he had no appetite, which has often been noted with chronic carbon monoxide poisoning. The blood should be examined at once for carbon monoxide when symptoms develop in a person working with an acetylene gas welder.

Softening of the Brain and Cerebral Hemorrhage.—Salomonson has noticed that since food has been scanty and dear, he has not encountered so many male cases of cerebral hemorrhage as in previous years, but on the other hand, the number of cases of softening of the brain has increased fourfold. The total figures for nearly seven years in his service are forty-six of the latter to thirty-eight of cerebral hemorrhage, but for the first four years the totals were only fourteen to twenty-one. Bread cards were introduced in 1915 and potato cards in May, 1916, and they were soon followed by great restrictions in fat and meat. During the last half of 1918 the ration of food was apparently at the lowest possible figure. There was first a general loss of weight and then a decline in the blood pressure. The pulse rate also declined, dropping to 40 or 50 or even less in the morning. The blood pressure declined to 7 or 8 cm. mercury, and Schlittenhelm has reported a decline to 4 and 5 cm. mercury. A further phenomenon for which Salomonson considers the undernourishment responsible was a weakening of the heart sounds at the base, evidently connected with the low blood pressure. The young and robust had their blood pressure decline the same as the elderly with pathologic vessels. Even with hard, tortuous vessels the pulse was remarkably weak. The circulation was thus below par throughout, and in terminal, more or less pathologic arterioles the circulation might die out completely. This is almost certain to entail arteriothrombosis and when this occurs in a cerebral artery a focus of softening results. The low pressure and the reduced pumping power of the heart deprive some of the smaller vessels of their full supply of nourishment. Among these the vasa vasorum suffer so that a vicious circle is set up. It is not a casual coincidence that the cases of softening of the brain have grown more numerous while apoplexy is becoming rarer. The prognosis according to his experience is much more favorable with the former than with the latter. Nearly all the cases of encephalomalacia improved notably under medical measures.

Tonsillectomy and Thymus Death. Burger reports the death of a youth of 15 under chloroform for tonsillectomy. The anesthesia and the operation had proceeded smoothly but immediately after the operation had been concluded, the heart action and respiration stopped. Necropsy showed the thymus more than twice the normal size, and the thymic-lymphatic status explained the fatality. This status seems to be particularly dangerous for gutter operations, and judging from Burger's own case and three he has found on record, the same is true of tonsillectomy. Köller's fatal case was the only fatality in his 6,000 tonsillectomy cases, and Kafemann's in 30,000. In one of the thymus death cases, death did not occur till the following day, after an interval of respiratory disturbance. In all the others death occurred at the close of the operation, before rousing from the anesthetic. Burger adds that there does not seem to be any certain means for detecting the thymic-lymphatic status beforehand, and that a retrosternal gutter may simulate a large thymus.

*Wassermann Tests in 1918. T. E. H. Thyssen—p. 825.

Wassermann Tests.—Thyssen found a positive response in 10.9 per cent. of the men and in 11.7 per cent. of the women among 738 hospital patients tested. In thirty-six cases the positive Wassermann was the only thing that suggested syphilis.

Nordiskt Medicinskt Arkiv, Stockholm

May 15, 1919, 51, Internal Medicine Section No. 4-5

*Phlegmonous Gastritis. H. Sundberg—p. 303.
*Symmetrical Gangrene. H. Marcus—p. 469.

Phlegmonous Gastritis.—Sundberg gives the details of 17 cases from the clinics at Stockholm and Upsala, and tabulates these and others he has found on record—a total of 215 cases of phlegmonous gastritis. His tabulation alone fills 60 pages and his bibliographic references 8 pages. The inflammatory process develops mainly in the submucosa. He says that Hedenius was the first to suggest the infectious origin (1871); streptococci have been demonstrated in 71 of 95 cases examined. In only 8 per cent. of all the cases listed were the patients of the well-to-do class; 25 per cent. of the total number had been hard drinkers. In the 17 personally observed cases, there was always a history of chronic gastritis, and the secretion of gastric juice was abnormally low. The inflamed mucosa is peculiarly vulnerable, and the deficient gastric secretion leaves it defenceless. Infection can occur by direct implantation of germs or by way of the blood. Pus in the vomit is the most instructive sign of the affection, especially when the amount is large and the intervals short. Another instructive sign is that the pains which may come to resemble those of a perforating gastric ulcer subside when the patient sits up after reclining. This was constant in his cases, and the high fever also testified against perforating gastric ulcer. In 33 per cent. of the fatal cases nothing was found to indicate peritonitis. Rational treatment can be only by resection of the diseased portion but spontaneous recoveries are known. Cases in which after an exploratory incision revealing supposedly incurable cancers, the patients survived for years afterward, may have been cases of phlegmonous gastritis on the road to healing. The death rate in his nonoperative series was 92 per cent. Cases in men are nearly three times more numerous than in women. The ages were between 20 and 60. High fever and general malaise, headache and thirst, with vomiting and sometimes violent and persisting hiccup often usher in the disease.

Symmetrical Gangrene. In Marcus' four cases the Raynaud disease developed as an acute infectious disease of the extremities, and in three of them a tumor was found in the mediastinum or pancreas which evidently interfered with the functioning of the vasomotor nervous system. Reviewing the literature shows the prevalence of symptoms showing disturbance in the sympathetic system, along with symptoms of septic infection, malaise, insomnia, mental haziness. Eruption of points is common, as also eruptions, pain, edema, neuralgic heart, enlargement of spleen, subsidence of the reflexes and tender points suggesting neuritis. The clinical picture thus combines features of both sepsis and rheumatism. There is evidently an inherited predisposition to vasomotor disturbances of the Raynaud type, and they develop under some provocative cause, catching cold, trauma, spinal processes or tumors. Syphilis may be a factor; no comprehensive data have been recorded in this line; in his own cases there was nothing to suggest inherited syphilis except possibly the tumors. He is now engaged on experimental research trying to induce symmetrical gangrene with unclamped direction.

Norsk Magazin for Lægevidenskaben, Christiania

*Aphasia. H. M. Berner—p. 742.
*Neurorecurrence After Arspenamin Treatment. J. H. Berner—p. 742.
*The Genius Epidemicus. IV. A. Magelssen—p. 749.

*Social Service for Children at American Hospitals. K. Uthelm.—p. 733.

*Neurorecurrence After Arspenamin Treatment. J. H. Berner—p. 742.
*The Genius Epidemicus. IV. A. Magelssen—p. 749.

Aphasia.—Krohn reiterates here the advantages of the method of examining persons with aphasia which he first described in the *Journal of Mental Science* in 1917. This takes into account all the psychosensory and psychomotor functions involved in speech, and thus renders possible a clinical nomenclature of the different forms of aphasia. It gives a critical survey of the various theories on aphasia and the speech center or rather speech region.

Changes in the Reflexes After Physical Exertion.—Krohn tabulates the findings in respect to the knee-jerk in forty-nine men just before and after a ski racing tournament covering a hilly course of 50 km. In all but two the knee-jerk was found afterward decidedly attenuated or abolished altogether. The race took nearly five hours, and the modification in the reflex was evidently a manifestation of fatigue. In ten of the men the response was weaker on the right side than on the left, suggesting that the right side was used more than the left.

Welfare Work for Children in American Hospitals.—Uthelm describes the work of the child health organizations, the classes for undernourished children, and other departments of welfare work for children in connection with certain American hospitals.

Neurorecurrence After Arspenamin Treatment of Syphilis.—Berner reports the case of a young woman who developed headache, vomiting and deafness six months after acquiring syphilis. It had been treated at monthly intervals with five injections of arspenamin. The Wassermann reaction was positive and the symptoms were those typical of neurorecurrence. They subsided under potassium iodid three times a day for three weeks, and then neo-arsphenamin. He reviews some German and Norwegian literature on neurorecurrence, and remarks that the prognosis should always be drawn with some reserve as although the symptoms may subside, even without treatment, there is usually some defect left in the functioning. The earlier and the more vigorous the treatment the better the outlook.

Influenza and Extremes of Temperature.—Magelssen discusses what he calls the genius epidemicus. He has noticed that certain weather conditions precede epidemics of influenza. This affects masses of people all around the globe, practically simultaneously, and this he thinks explains the pandemics by rendering the people susceptible to disease. A chart showing the epidemics of influenza at Christiania since 1847 and the temperature during these eighty years reveals a close connection between certain weather conditions and the epidemics. In the year preceding the epidemics the winter temperature had been unusually cold, and the following spring had come on suddenly, prematurely warm, and the summer was unusually hot. This abrupt transition from cold to hot may modify the heat regulation in the body in some way, and thus reduce the resisting power to diseases in which the vasomotor tone is low and the vitality and vital functions are depressed. In these characteristics influenza resembles the symptoms which often develop on moving from a temperate to a tropical climate.

His data suggest that the limits between influenza, catarrhal fever and ordinary colds are not very decided, and that the virus is made up of the same familiar germs of old. The susceptibility to the virus and the virus and the intensity of its action are the results of a temporary constitutional weakness which in turn is the result of the action of the temperature. His charts indicate that the weakening of the constitution from this cause makes its influence felt for about three years at least. The practical conclusion follows that in periods of epidemic disease it is wise to refrain from needless exposure to extreme cold or extreme heat and from sudden transitions. One reason perhaps why the young and robust suffered most from influenza was because they exercised so much in military drill, in athletics, in dancing, etc., and were gathered in underheated or overheated rooms. Prolonged diaphoresis and bed rest seem to offer the best prospects in treatment.

THE INFLUENCE OF THE WAR ON PREVENTIVE MEDICINE AND PUBLIC HEALTH*

C. ST. CLAIR DRAKE, M.D.

SPRINGFIELD, ILL.

Those who have observed the thought and tendencies in preventive medicine of the present time must be impressed that the war will mark a definite turning point in public health activity and that there lies before us a period of reconstruction and reorganization in methods of health administration. The dominant thoughts underlying this readjustment are that both military and industrial power are dependent on man power and that the strength and efficiency of our man power will be determined, in the last analysis, by the health of the individual. In this readjustment, and born of our war-time experiences, disease prevention will be regarded as more important than disease suppression, and health promotion will take precedence over both. The public health administration of the future will be a forward-looking administration. While giving attention, as it has in the past, to the specific sources of illness, it will devote itself largely to the prevention of human ailments by the development of maximum health and, in pursuing this policy, it will deal with the individual more than ever before.

During the war, health became a matter of the utmost importance. It acquired a new practical value which, for the first time in our national life, has come to be appreciated by all intelligent people. The war also gave us some valuable and, incidentally, some disconcerting facts in regard to the physical condition and health of the people, and afforded an opportunity to try out the efficiency of modern preventive measures unrestricted and unhampered by prejudice, ultraconservatism or narrow opinion. As never before, public health work was given adequate financial backing. Efforts in disease prevention were made without the embarrassments arising from considerations of cost. For the first time we were able to demonstrate in a large way that good health is actually a purchasable commodity, and the American people have passed favorable judgment on the results of that demonstration.

This progressive policy, adopted in dealing with the health of the military forces, was doubtless due, to a large extent, to the fact that we were enabled to

observe the experiences of European warring nations for some time before we became participants and, further, that we entered the war at a critical period when everything depended not only on the character of our military forces, but also on the productive ability of our industries. We had been awakened to the urgent necessity for the maximum of nation-wide physical efficiency.

The people as a whole have learned a new lesson as to the importance of individual and national health in time of war. They have also had it impressed on them that, while hostilities have ceased, the war is not over—that the period of reconstruction will make large demands on the physical resources of the nation—and they stand ready to continue and extend those health activities which have proved effective during the past two years.

The finding of the exemption boards and of army medical examiners came as a first awakening shock, disclosing, as they did, a surprising prevalence of physical disability, largely preventable in character, leading to the rejection, in the average community, of almost 20 per cent. of the young men who were presented for military service. These findings, incidentally, demonstrated conclusively the value of one of the modern means of health promotion too generally ignored in the past—the periodic, physical examination of presumably healthy persons for the detection of early disease.

Of the disclosures made by the various examining boards, none excited more general comment than that of the great prevalence of venereal diseases and tuberculosis—the two diseases which, in many ways, have been longest neglected in our public health activities. The grave apprehension which had already attached to tuberculosis in the European nations and the prompt action in the United States, in providing a large corps of tuberculosis experts for army service and in establishing large sanatoriums for returned consumptive soldiers, changed the attitude of the American people very radically toward that disease and indicated the necessity for more extensive antituberculosis activities in the future. States and communities in which restrictions and regulations for the control of tuberculosis have been largely ignored on account of indifference or prejudice now find the people and the medical profession ready and anxious for any reasonable restrictive action. In one state alone, the lessons from the war have made such impression that while few public sanatoriums existed prior to that time, forty such institutions have been created by popular vote within the past two years, each with its attendant dispensaries and community nursing service.

*Chairman's address, read before the Section on Preventive Medicine and Public Health at the Seventieth Annual Session of the American Medical Association, Atlantic City, N. J., June, 1919.

RECOGNITION OF IMPORTANCE OF VENEREAL DISEASES

The awakening to the importance of venereal diseases and the change in public sentiment in regard to them have been even more spectacular. Health officers and the general public have always been reluctant to deal with these ailments frankly, and the campaigns of education have been generally half-hearted and weak. Certain press associations, reflecting the common sentiment of a few years ago, passed resolutions disapproving the use of the words "gonorrhea" and "syphilis" in the public prints. In view of this timid policy, and possibly as a result of it, the recently published statements of Vaughan and Palmer¹ are significant. While all other communicable diseases which sorely beset the armies during the Civil War have been greatly decreased and, in some instances, practically eliminated, there was found to be a very large increase in gonorrhea in the army of 1917 as compared with 1861.

The manner in which the federal government, through its military medical departments and under the provisions of the Kahn-Chamberlain law, have attacked the venereal disease problem, not only of soldiers, but also of the civil population, established a new policy and line of action from which the health officers of the future will never recede. Venereal diseases are being discussed before general audiences without hesitation, and educational and restrictive measures are being carried out such as would not have been possible had it not been for the accent placed on the subject when the nation was at war. The method of dealing with individuals who are presumably spreaders of venereal infection is a striking index of our entirely changed point of view. In many communities, prostitutes are now being apprehended, but, instead of being fined or committed to jail, which could have no influence whatever on the prevention of disease, these unfortunate women are sentenced, but the sentence is suspended so that they may be committed to general hospitals for treatment and from which they are discharged only when they have clinically recovered or when the best obtainable evidence indicates that they are no longer sources of infection. This is another indication, incidentally, of the individualization in health work which will unquestionably be a large factor in the health programs of the future.

CHILD WELFARE WORK

The acute problem that has confronted the European nations, particularly France and Belgium, of a decreasing birth rate and a greatly increased mortality, has attracted world wide attention and has centered unusual interest on the field of child welfare, and this interest has been accentuated by the realization that much of the physical inefficiency disclosed by examining boards might have been avoided had there been more intelligent thought on the subject of child conservation in the past. It is, of course, generally recognized that the span of human life has been increased about six years during the past generation and that it is possible further to extend life expectancy; and it is further recognized that this gain in the life period is largely due to the prevention of infant mortality, so

that child welfare work appears at present to be the most hopeful field for public health endeavor and the one promising the most direct and definite returns.

In the attempt to reduce infant mortality, as carried on throughout the nation today, the chief efforts are directed toward keeping the well baby well, following the policy of health promotion rather than that of direct disease prevention; and the public health organizations are devoting themselves to the development of the individual child through better baby conferences, infant welfare stations, community nurses and other factors that are relatively new to public health organizations.

EXTENSION OF CLINICAL ACTIVITIES

This individualization in health work, illustrated in what has been done during the war in tuberculosis, venereal diseases and child welfare, foretells a definite new departure in the public health administration of the future—the development of extensive clinical activities. In the past, with certain exceptions, health departments have taken no part in diagnosis except in the contagious and infectious diseases of epidemic type and through the services of diagnostic laboratories. If the policies adopted both here and abroad during the war are to be continued and extended, it seems inevitable that health authorities must render increased diagnostic and clinical services, including the early diagnosis essential to recovery from tuberculosis; the diagnosis of venereal diseases and the treatment of such cases especially for indigent persons; the development of well baby clinics and clinics for the reeducation of victims of poliomyelitis, on the diagnosis and treatment of trachoma, and so on. To carry out this work successfully, the various health departments will be compelled to employ physicians of highly specialized skill, and will necessarily have to make provision for far more generous compensation than is customary among public health agencies at the present time.

This extension of clinical service by health authorities, contrary to the opinion occasionally expressed, will prove directly beneficial to the medical profession as a whole. It is a matter of common agreement, wherever such public clinical work is undertaken, that, as a result of its educational influence, there is a decided and immediate increased demand for professional service among the patients of private physicians. In this way, the results of public health clinical work extend much farther than merely to that part of the public which the clinics themselves actually serve.

The work that is being done by the Department of Reconstruction of the United States Army, under the leadership of Col. Frank Billings, suggests possible extensions of public health activity since, in the broader and newer conception, public health work includes every activity that will increase the physical efficiency of the individual or community or which will restore the physically unfit to the highest point of health. To what extent this policy of reconstruction can be properly utilized in the future is open to question; but, in the development of our future program, it is entitled to serious consideration. Certainly the work that has already been done by some health departments in the training and reeducation of persons crippled by poliomyelitis has been so gratifying and far-reaching as to justify the belief that reconstruction will one day be a part of public health promotion.

¹ Vaughan, V. C., and Palmer, G. T.: *Venereal Diseases in the Central Trench and North Arm of the United States During the Months from September, 1917, to March, 1918*, J. Lab. & Clin. Med. 14:635 (Aug.) 1918.

DEVELOPMENT OF HEALTH OFFICIALS FROM
MEDICAL OFFICERS

It is obviously impossible to discuss at this time all the phases of preventive medicine influenced by the war, but one factor which will have a tremendous effect in altering the public mind in regard to health administration is the return to civil life of thousands of physicians who have received intensive training in sanitation and preventive medicine during their military service. It is to be expected that a large number of these physicians, having had their first experience in public service, will be reluctant to return to private practice, and there may be developed from them an unusually competent group of health officials; while those who return to private practice will exercise a new and salutary influence in their own communities.

POPULAR INTEREST IN PUBLIC SERVICE

In addition to this, there will be scattered throughout the nation approximately 4,000,000 young men who have had impressed on them in no uncertain terms the paramount importance of disease prevention and health promotion, and who have seen the advantage of yielding cheerfully to reasonable health regulations. These young men will naturally assume the leading part in their community affairs during the next generation and, with the guidance of public health departments of broader vision and larger resources, will materially influence the history of preventive medicine of the future.

The greatest changes in health development, however, will come out of the tremendous interest in public service created during the war and which found expression in the upbuilding of many large extragovernmental organizations engaged in various phases of patriotic and philanthropic work. With the war over, these organizations have been casting about for desirable fields for the expenditure of their energies and, in the majority of instances, they have settled on some phase of public health activity. This has created a situation which is disturbed and unique, full of possibilities for splendid progress and equally full of possibilities for confusion, overlapping, conflict and wastefulness.

This great popular interest will doubtless serve to stimulate the governmental health agencies to greater endeavor and will overcome official apathy and ultra-conservatism. If these volunteer agencies can be properly coordinated under governmental guidance, they can be a tremendous influence for good. Unguided, however, the very multiplicity of organizations, the ease with which private funds are now obtainable for health purposes, and the lack of uniformity in views and methods will lead to wastage in money and effort and to the ultimate weakening and discredit of public health endeavor. The war has left us in a critical condition, full of possibilities for good and bad, in which sound judgment and firm policy by health authorities are imperatively needed.

THE HIGHER AND BETTER EDUCATION
OF THE DENTAL STUDENT*

EUGENE S. TALBOT, M.D.

CHICAGO

The object of the formation of this section was to assist in establishing a closer relationship between the mother profession of medicine and the younger specialty of dentistry, and eventually to place the specialty on a medical basis. How much has been accomplished in this direction since its formation, history has shown. Certainly the interest displayed by the ablest men in the medical profession by their presence, in reading and discussing papers, demonstrates that they have done more than their share in placing this section on an equal footing with the other sections in this great Association.

In my early practice of dentistry I soon realized that if I was to become a successful practitioner, I must know more of pathology than I had obtained in the dental school. To obtain that knowledge I must attain a medical education; and although it was a hardship for a man with a family to abandon practice for two years, I have been more than compensated by the broader knowledge and fellowship which I have acquired. Every man starting out in life should have high ideals, and those ideals should be so broad and advanced that it requires a lifetime to accomplish the end.

The ideals firmly fixed in the minds of those men who organized this section were that dentistry, being a part of the healing art, should and must be a part of the medical profession, and that a thorough medical education was just as necessary for treating diseases in the mouth as diseases in any other organ of the body. The dental schools have begun to realize this fact, for since this section was established, the college course has been extended from a two-year to a four-year course, the entire length of a full medical education.

It is rarely the lot of man to live to see his ideals developed to their highest attainments. Nearly all of the organizers of this section have passed on. With one exception, however, they all lived to see great advances along the lines of their ideals.

The stomatologist with his medical education is on an equal footing with the men practicing in every other department of the healing art, and is, therefore, freely consulted in the most difficult and obscure etiologic symptoms of disease in which the mouth, jaws and teeth may possibly be a factor.

As time goes on and the etiology of disease becomes better understood, the relationship of the general practitioner and the stomatologist must become more intimate. It stands to reason, then, that the man who treats the mouth, jaws and teeth must be a medical specialist, equal to the best medical specialist in other branches of the healing art.

It may be of interest to the members present to know that in the thirty-nine years of its existence, this section has not received a single paper on the subject of the mechanics of dentistry. All papers presented and read before the section have been on the subject of pathology or on some subject of interest to both

* Chairman's address, read before the Section on Stomatology at the Seventieth Annual Session of the American Medical Association, Atlantic City, N. J., June, 1919.

Is Your Community Fit?—What effort has been made to ascertain whether or not your milk supply is safe? Diphtheria, scarlet fever, septic sore throat, typhoid fever, dysentery, all may be spread by unsafe milk. A system of inspection and efficient pasteurization will protect people from milk-borne diseases. If your community is too small to bear the expense of dairy inspection, it should at least enjoy an adequate system of pasteurization under proper supervision.—*Pub. Health Rep.*, April 25, 1919.

physicians and stomatologists. By adopting this plan, physicians have been as much interested in reading the papers of this as of other sections.

On the other hand, many dentists subscribe for *THE JOURNAL* or obtain access to it through physicians in their vicinity. Through this section, therefore, there has developed a closer relationship between medicine and dentistry. The future of this section has a prosperous outlook. Focal infections arising from diseased teeth, and also the associations as a result of the war, have drawn the stomatologist and the medical practitioner into closer relationship. We have arrived at the period when one cannot possibly get on without the other. Physicians are seeking specialists who are qualified to assist them in a proper diagnosis of disease, and naturally associate with those who are medically educated. In the future, therefore, the man who wishes to be a success in his specialty must have a medical training.

The future of the section is assured. Dr. Black comes to us as secretary in the fulness of youth and experience. I am sure that he will direct the future welfare of the section to a higher and broader usefulness.

WOUNDS OF THE FACE AND JAWS

Modern methods of war and its destruction have developed a line of surgery of the face and jaws that could not have been produced in any other way. Injuries due to explosive shells have caused more extensive wounds than can be produced in any other way. These include fractures, destruction of bone structure, and lacerations of the associate soft parts.

We have with us at this meeting stomatologists who have been most active in the different branches of this service and who will demonstrate the latest methods of teaching of the treatment of wounds.

FOCAL INFECTIONS

It has been shown and accurately demonstrated that 95 per cent. of all roots of teeth are imperfectly filled. In other words, owing to irritations in the process of treating and filling the roots of teeth or to the decomposition of tissue after filling, pathologic changes occur about the roots, as shown by the roentgen ray and microscope. These pathologic changes have been known to the profession for the past eight or ten years, and yet the same methods of treatment are applied today as formerly. How long would the medical profession continue to perform an operation on any other tissue of the body, knowing that the technic was so faulty? My researches on animals during the past twelve years,¹ show that the least irritation produced in the treatment of the roots of the teeth will cause absorption of the alveolar process and roots, with irritation and inflammation of the periodontal membrane.

Abnormal collateral arterial development in the roots of the teeth and the abnormal development of the granular layer of Tonies—researches of which have not yet been published—demonstrate the almost complete hopelessness of permanent success, no matter how well the root may have been filled.

The number of focal infections and disturbances from faulty root fillings, local and systemic, is appalling. The average dentist, not being grounded in pathology, does not and cannot appreciate the seriousness of his faulty treatment. A different method of root

filling must be immediately instituted or devitalized teeth must be extracted. A rule which I have adopted is that a patient's health is worth more than all the natural teeth.

FAULTY METHODS OF PRACTICE

From time to time, in the past thirty years, I have repeatedly called the attention of the profession to the fact that modern dentistry is producing more disease than any other one cause. The profession is beginning to realize the truth of this statement. Since the first dental college was established, there has gradually developed a method of practice of mechanics regardless of pathologic results. The method of practice, at best, has benefited the individual patient only for the time being. On the other hand, after operations are performed, disease has followed in almost every instance.

Our present method of treatment has not benefited the race as a whole. Decay of the teeth and deformities of the jaws have increased from generation to generation until at the present time hardly a child under 12 years of age can be found free from tooth decay and deformities of the teeth and the jaws. Since our present methods of procedure are faulty, we must resort to radical changes in treatment and devote our entire attention to preventive measures.

MEDICAL TEACHING VERSUS DENTAL TEACHING

The wonderful progress made in medical teaching in the last fifteen years should be an incentive for the better education of the dentist. In 1904 there were about 156 medical schools in this country. Through the influence of the Council on Medical Education the standard has been raised and the number of schools, by combining one with another or by dropping some out altogether, has been reduced in the last fifteen years to eighty-five. From 80 to 95 per cent. of these schools now require for admission two years of work in a college of arts and sciences, as compared with only 2.5 per cent. of all colleges holding that requirement in 1904. In some of the schools there has been a continuous session of the four quarters plan, whereby the student is allowed to select any three quarters of the year that best suit his convenience to complete his yearly term.

The chairman, Dr. John M. Dodson,² in his report asked: "Is there a logical reason why the student should not be allowed to utilize the summer months in full-time medical work in residence and thus complete the present requirement of four sessions in three calendar years, his year of internship in a fourth year, and so enter into active practice a year earlier than has been possible under previous regulations?"

Under the four quarters scheme, seven weeks may be provided for vacations so that attendance on the four quarters is no hardship for the student in good health who desires to avail himself of the privilege.

Dr. N. P. Colwell,³ in stating the further needs in medical education, said that an improvement still greatly needed in medical schools concerns the methods of clinical instruction of medical students. Students should be enabled to complete most of their didactic courses in the third year, so that most, if not all, of the time of the fourth year may be devoted to

² Dodson, J. M.: Problems in Medical Education, *J. A. M. A.* 72:81 (March 13) 1919.

³ Colwell, N. P.: Recent Progress and Further Needs in Medical Education, *J. A. M. A.* 72:822 (March 13) 1919.

clinical courses for groups of about six students each in the hospital wards.

These changes, so necessary in medical schools, are just as necessary in the dental schools. I have advocated these changes in dental teaching for a number of years. Why should a student spend four years in college when he can save a year far easier than the medical student, since only half of his curriculum is given up to didactic teaching and the other half to the mechanics of dentistry? The mechanics of dentistry can very easily be taught in the summer months, and the fundamental principles of medicine and dentistry may be left for the winter months. The curriculum can be so arranged that the student can have from five to seven weeks' vacation, which is from three to five weeks longer than the vacation of the average professional man.

I have held for many years that the dental school could not make a professional man out of the student by the present method of teaching, even if the course should be extended to six or eight years. There are two grades of dental colleges in the United States; those that are an actual part of universities or colleges, and those that are not. Those that are a part of universities have nothing to do with the matriculation of students. Those that are not have everything to do with the entrance requirements of students. There is an unwritten law among the dental schools that all students entering must be either graduates of a high school or they must successfully pass an examination covering the average high school requirements. The result is that a large percentage of the students entering the dental schools other than those connected with universities or colleges have not an education equal to that of our common schools. It is possible that the dean can explain how these students enter.

Having entered, this uneducated student immediately begins to ascertain what is necessary for graduation. He soon learns that the mechanics of dentistry is the essential thing, since he cannot graduate until he can successfully perform certain operations on the teeth and make artificial dentures. Most of his thought and time is spent along these lines. Courses are pursued in the departments of anatomy, physiology, pathology, bacteriology, chemistry, etc., but are not considered of so much importance as it is the mechanics of dentistry that counts toward graduation and practice.

The student begins his mechanical training almost as soon as he enters school. The result is that the ignorant young man, following the line of mechanics, on graduation enters practice as a mechanic rather than as a professional man. As I have already stated, by this method of teaching, a six-year or eight-year course would not improve the mentality or standing of the individual in the community.

Again, students entering the dental school from the farm, shop and factory are unmindful of what is required of them when they enter practice. They pay their fee and expect to be qualified to serve the public successfully when they enter practice. They soon learn, however, that a broader knowledge of the essentials of medicine is necessary to cope successfully with the conditions presented by their patients than they had received in their dental training.

The remedy is easy. Make a professional man out of the dentist, as well as a mechanic. Require the student to take one or two years' work in the arts and sciences. This will relieve the dean of the dental

school of all responsibility of the preliminary requirements. The first two years of work in the dental school should be given up to didactic teaching. The student should not be permitted to operate on patients or perform mechanical laboratory work until the third year. All or nearly all of the last two years may be given up to the practical side of the specialty. The preliminary training in the laboratory of the academic and premedical courses will give the student all the finger training that is necessary to prepare him for his dental activities.

BOOK READERS

There are about 45,000 dentists in the United States. Out of that number not over 500 buy books relating to their specialty, or read them. The reason for this has already been explained. Dentistry is a part of the healing art. There is no reason why the dentist should not be as well educated as the physician and hold an equal position in the community. It is high time that the profession itself awoke to the situation and demanded better qualified graduates from our dental schools.

UNIVERSITY SCHOOLS

This section has always used its influence on the side of the university schools. Your secretary has made it a point to attend the annual meetings of the Dental Faculties Association of American Universities when possible, and has always been received with much cordiality. He has read and discussed papers relating to the higher and better education of the dentist. I would suggest that the executive committee of this section be made a standing committee to attend the annual meetings when possible and use its influence on behalf of this section to suggest improvements in special teaching and to encourage the teachers in their efforts to place their schools on an equal footing with other departments of the healing art.⁴

TRENCH FEVER IN THE AMERICAN EXPEDITIONARY FORCES *

HOMER F. SWIFT, M.D.
NEW YORK

Trench fever is a disease that has been recognized and differentiated from other morbid conditions during the recent war. While there is little doubt that it existed previously in some place or places, there is no doubt that to all medical officers it presented new problems in diagnosis, prognosis and treatment.

There are descriptions of the disease and reports of its occurrence in all armies on the western front. But from the mass of reports it is impossible to determine the original source of the infection or the line of spread from area to area. The constant movement of troops in an army, the ever changing composition of every unit, make epidemiologic studies very difficult and accurate reconstruction of the mode of diffusion of a well known disease virtually impossible. When we consider that on the western and eastern fronts and behind the lines there were troops from nearly every country in the world, it is easy to understand how an unknown disease, which might have been endemic in

4. The discussion on this article will be found on page 830, this issue.

* Read before the Section on Practice of Medicine at the Seventeenth Annual Session of the American Medical Association, Atlantic City, N. J., June, 1919.

some out-of-the-way country, might rapidly gain a foothold among men who had not developed any natural immunity.

The difficulties in collecting accurate statistics concerning trench fever were increased by the recency of

Fever, which is the most common of all the symptoms, does not always follow any one course. Various efforts have been made to separate the types of fever into two or three groups. The most comprehensive classification is that of the British Expeditionary Force Trench Fever Commission:

- (a) Relapsing, either regular or irregular.
- (b) One single short bout resembling influenza.
- (c) Continuous fever extending over a longer period, resembling in its form typhoid or paratyphoid fever.

While such classification is useful, it should be emphasized that the cases do not always fall into one of these groups. A case with regular relapses may later have long continued low-grade fever. The febrile relapse may occupy only four to six hours, and hence may be missed if only morning and evening temperatures are taken. Again, the entire fever may continue less than forty-eight hours. The case with three or five days continuous fever without a subsequent relapse may be easily mistaken for influenza.

Charts 1 and 2 illustrate the different types of fever that may occur from inoculating different individuals with the same strain of virus. They are abstracted from charts of the volunteers inoculated by the American Red Cross Trench Fever Commission.

The other clinical manifestations of trench fever, taken separately, are even less diagnostic. The sudden onset with headache, general muscular pain and anorexia is seen in other acute infections. The "pink eye" resembles the conjunctival congestion so frequent in influenza. The nystagmus, elicited on extreme lat-

Chart 1.—Different types of fever that may occur from inoculation of different persons with the same strain of virus. In the next to the last case the temperature was normal from the twelfth to the fiftieth day. In this chart the temperature after the blank space marks the febrile relapse on the fifty-first and fifty-second days.

its discovery. It was never made a reportable disease because the conditions which must be fulfilled to make reporting compulsory could not be clearly defined. For many months most medical officers were ignorant of the existence of the disease, let alone its manifestations in the patients under their care. To the entire medical profession the nature of the disease was more or less a mystery. The fact that the term "pyrexia of undetermined origin" (P. U. O.) was applied in the diagnosis of most cases is sufficient indication of the general attitude toward the malady. Although the specific nature of the infection was established by McNee, Brunt and Renshaw in 1916, it continued to be confused with other acute infections. The term "pyrexia of undetermined origin" was applied to all these conditions, even though it usually implied trench fever.

DIAGNOSIS

While it is fairly easy to describe the general disease trench fever, it is much more difficult to make an exact diagnosis in many individual cases. This difficulty arises from the variety of manifestation.

Chart 2.—Different types of fever that may occur from inoculation of different persons with the same strain of virus.

eration of the eyeballs, may be present normally and is seen in other febrile states.

An enlarged spleen is found in typhoid fever and malaria, either of which may be mistaken for trench fever. The trench fever spleen, however, is harder than that found in typhoid fever and not so large as that often present in malaria.

The trench fever rash may be mistaken for typhoid rose spots, if the evolution of the individual macules and the relation of their appearance to the other manifestations of the disease are not carefully recorded.

The neck pains may suggest meningitis; the pain in the back, lumbago; and the abdominal pains, appendicitis or acute peritonitis. The joint and muscle pains are often mistaken for subacute or chronic rheumatism or myalgia. The painful joints in trench fever are not swollen. The shin pains in trench fever are the most characteristic symptoms of the disease, although they are not always present. Similar pains are described in dengue fever, and in soldiers after long marches or after standing in mud or water for long periods.

There is no laboratory method which has a direct diagnostic value. Leukocytosis is usually found during the periods of pyrexia, but leukopenia is occasionally as marked as in typhoid fever or dengue.

The reason for reciting these confusing points is to show that a correct diagnosis is not readily made in a single examination or from the consideration of a few symptoms or signs. It is only by careful daily examinations and the recording of the findings, as well as by the elimination of other diseases, often by laboratory methods, that the largest proportion of correct diagnoses can be made.

The preceding remarks apply to the difficulties in making a diagnosis in every army under field conditions. Certain special difficulties existed in the American Expeditionary Forces. During the period when most of these cases occurred, we were passing through the influenza epidemic. It is usual for physicians to apply the name of the most prevalent acute disease to all pyrexias of undetermined origin that come under their observation. In this way they make the largest number of correct diagnoses, but at the same time

Influenza was constantly present in the American Expeditionary Forces, there being 190,689 cases reported from July, 1917, to May, 1919. In addition there were 21,939 cases of pyrexia of undetermined origin. It is easy to understand how a number of cases of trench fever might have been missed in these 212,628 cases.

ETIOLOGY AND COURSE

Both the British and American Trench Fever Commissions have shown that the body louse is the chief

many incorrect ones. Trench fever and influenza closely resemble one another at the onset. Many cases can never be differentiated. Most cases require prolonged observation and continuous temperature records. In the rapid movement of patients from one hospital to another, the temperature records frequently were not sent with them. The temperatures and pulse rates were often taken, but not recorded, because there was no convenient place to record them. It is self-evident that the field medical card should have a special blank for the recording of temperatures. Then the degree and the time of fever would be noted, and the medical officers in the hospitals in the rear would not be at a loss to know what had gone on in the forward areas. This knowledge is important for the proper care of both sick and wounded.

agent in transmitting the virus from man to man. The British commission feels that the chief mode of inoculation is by the scratching of the feces of infected lice into the skin of louse infested men. The American commission showed that infection did occur following the bite of infected lice, even when there was no visible excoriation of the skin. The elucidation of the exact mode of inoculation is purely an academic problem, for it is certain that lice living under normal conditions can easily transmit the infection. The virus remains active for a long time in dry louse feces. It is also present in the urine of trench fever patients, its resistant qualities being shown by the fact that the concentration of such urine by drying does not kill it. It will pass through a Chamberland filter. Its thermal death point is above 60 C. All these characteristics show that it belongs to the group of resistant filterable viruses.

The course of the disease in human beings is different from that ordinarily seen in most other acute infections. In many ways it resembles malaria. The number of relapses is variable. It tends to become subacute or chronic in many patients. In some there are long periods of latency, the patient appearing per-

fectly well, with later an acute exacerbation. There is no known specific cure. Recovery is evidently due to the development of some type of immunity. Lice may take up the virus from a patient weeks or months after the onset of the disease. Just as there is no known laboratory method of diagnosis, so there is no known method of determining when a patient may be no longer a source of infection.

PROPHYLAXIS

From the foregoing observations, three factors must be considered in preventing the spread of the disease: (1) the louse as the transmitting agent; (2) the human

delousing apparatus are necessary to keep all the troops of an army vermin free. It is needless to dwell on the general lack of these requisites during an active campaign.

Our troops must have come into contact with many soldiers with trench fever. The disease was very prevalent in the British army. At least ten of our divisions spent a portion of their training period in the British area. Reports from American base hospitals attached to the British army show that a number of our soldiers were infected with the disease in this area, even though the proportion was not so high as among British troops. It is impossible to state accurately the

foci of infection, and (3) the resistant nature of the virus.

The extent of lousiness of soldiers under field conditions is well known by many medical officers. Peacock reported that at least 95 per cent. of British soldiers living in the trenches were lousy. Many sanitary reports from our own army indicate a similar degree of infestation among American troops. Among the first sixty American volunteers who reported to the American Trench Fever Commission, 38.3 per cent. were infested, even though the entire detachment was supposed to have been recently deloused. It is remarkable how soon an entire division will become infested after an ordinary delousing. Constant, thorough inspection and easily accessible bathing facilities and

degree of prevalence of the disease in the French army. We know, however, that it did exist. It was present to a considerable degree among the German soldiers, so that our advancing troops were exposed to infection in the captured trenches, and the troops of the army of occupation were exposed to a certain extent in German billets and barracks.

INCIDENCE OF TRENCH FEVER IN THE AMERICAN EXPEDITIONARY FORCES

Table 1 shows that only a small number of cases of trench fever were reported in the American Expeditionary Forces. These figures are probably far from representing the actual number of cases. All of the reasons for making diagnosis difficult were constantly

in operation. Many of the diagnoses were missed because of the rapid movements of the sick, but probably many more were missed because medical officers were not acquainted with the manifestations of the disease. This statement is borne out by the experience in the Third Army. Early in January, 1919, after the troops were in the areas they were to occupy permanently, and most of the sick were under continuous observation in the evacuation hospitals, a number of cases of typical trench fever were brought to light.

occurred in December. In fact, many of the patients stated that their trouble began at the time of the march forward from the Argonne region into Germany. Taking the figures as they stand, however, we see that over three-fourths of the cases occurred in two divisions, the Forty-Second and the Second. The effect of delousing and removing patients from their division is well demonstrated, for after the third week in January the number of cases fell off rapidly in each division. The distribution of cases throughout the division, corps

An attempt was then made to acquaint all medical officers in the field and evacuation hospitals with the manifestations of the disease, the mode of transmission, and prevention. By means of informal reports, the medical officers of the various units from which cases came were urged to insist on better delousing measures.

Chart 3 shows the incidence and distribution of cases in the various units by weeks for the first three months of this year. All of the reports were made from the evacuation hospitals. In several of the cases reported between the 1st and the 11th of January, the onset

and army troops down to units as small as companies is shown in Tables 2, 3 and 4.

Cases were identified from 162 different companies. From each of 110 of these companies one case was diagnosed, from thirty-five companies two cases, from ten companies three cases, from five companies four cases, from one company five cases, and from one company seven cases. Thus, while the infection was widespread throughout the army, it was not very extensive in any one unit. The figures suggest that foci of infection had been present among the troops only a short time. It is interesting to note, however, that the two

divisions with the heaviest rate had been overseas since 1917. The lower rate in the other old division, the First, is in line with the general low sick rate in that division.

By the first of February, delousing facilities were fairly adequate. This month the rate dropped to less than half that of January, and in March it was about one fourth the January rate. The continuation of the disease in February and March was probably due in part to infection incurred in January, and in part to infection contracted elsewhere. At this time, large numbers of men were going on leave to various parts of France where troops from other units of the American Expeditionary Forces were also on leave. Leave, with the diminished medical supervision and the necessary crowding on trains and in billets, was a fruitful source of infection of all kinds.

A comparison of the number of reported cases (300) in the entire American Expeditionary Forces in the first three months of 1919 with the number from the Third Army for the same period reveals the fact that five sixths of the reported cases were from the Third Army. In spite of the heavy incidence in two of the divisions, it is highly improbable that one seventh of the entire American Expeditionary Forces would furnish five sixths of the cases, especially when several of the divisions then in France had been more exposed to trench fever. We are, therefore, forced to conclude that a considerable number of cases existed throughout the American Expeditionary Forces that were never recognized.

POSSIBILITY OF SPREAD

The return of so many soldiers to civil life will doubtless result in distributing foci of infection throughout the country. Every possible precaution is being taken to see that the troops are completely deloused before embarkation and demobilization. Nevertheless, the possibility of long latent periods and late relapses, as well as the power of body lice to take up the virus during the late periods of the disease, must be borne in mind. Lice are not confined to armies. In our cities there is constant danger of transmission of any louse-borne disease if human foci of infection exist.

The fact that trench fever is not fatal has naturally caused it to be disregarded when there were so many more urgent conditions demanding the attention of the medical officers. As an economic problem, it must be recalled that, on the average, a trench fever patient is incapacitated for six weeks. Often the infection persists for months. The effort syndrome is a not infrequent sequela; indeed, this symptom may be an indication of the persistence of the infection. It is, therefore, important to keep in mind, as after-war problems, both the possibility of the spread of the infection and its effect on discharged soldiers.

ABSTRACT OF DISCUSSION

DR. WILLIAM S. THAYER, Baltimore: The only way to learn the practice of medicine is by practice and experience, and there is no greater demonstration of that than what has been shown in the paper by Dr. Swift. Dr. Swift went up into the active area and found trench fever; the rest of us did not find it.

DR. ERNEST ZUEBLIN, Cincinnati: I think any new disease of which we have heard so much is liable to arouse our curiosity, and I think we are really fortunate to have Dr. Swift tell us about his experience. With the discussion of a

new disease such as trench fever, many questions arise which I would not like to touch on at the present moment, but first I would like to know whether in addition to the cardiac manifestations any other syndromes have been encountered; second, whether the means of controlling the lice have been sufficient to prevent any further propagation of the disease; and third, how long a time is required, that is, for how long a time the patient is still to be considered as infective and a danger to the community, and what are the means available to determine the extent and duration of a cure from the disease.

DR. HOMER F. SWIFT, New York: I forgot to mention that the disease is not fatal. We do not know of any patient who died as a result of trench fever. I think in the British army a large proportion, 50 per cent., of the cases of D. A. H., had trench fever. Another late symptom is the persistence of leg pains and lumbar pains. Many of these patients come in with the diagnosis of chronic rheumatism or chronic lumbago, and when you go back and reconstruct their histories, you will find that they began with definite relapses every few days. Unfortunately, we have no way of telling how long a patient will remain a source of infection. We have no laboratory method of diagnosing the disease, and we have no way of telling how long that patient will infect a louse before a louse will infect a human being. I think as long as a patient is showing active symptoms of the disease he should be a subject for isolation, not strict isolation as in measles, but isolation from infestation.

The second point as to the amount of heat necessary to kill the virus, you will see that from 56 to 60 C. kills the lice and also kills the eggs, so that for ordinary purposes heating clothes at 60 C. is sufficient to delouse. That is not sufficient to kill the virus in the feces of the lice or the virus in the clothes that may have come from urine or saliva, so that it takes a higher degree of heat to disinfect clothes which have come into contact with trench fever patients, as well as disinfect them.

RECURRENCES AFTER OPERATIONS FOR EMPYEMA*

FRANKLIN A. STEVENS, M.D. (BOSTON)

Lieutenant, M. C., U. S. Army

TAKOMA PARK, D. C.

The final results of the treatment of empyema of the chest can be ascertained only after the elapse of a considerable period. This period is of variable length and depends on the organism causing the infection, on the size and shape of the cavity, and on the particular method of treatment adopted. There is a minimum possibility of recurrence when the sinus has been completely obliterated by a gradual approximation and cicatrization of its walls. Recurrences are more common when an empyema is allowed to close while a cavity containing air still exists. If the Carrel-Dakin treatment has not been used to sterilize the cavity, the percentage of recurrences is particularly high. In addition, there are two other possible causes of reaccumulations of pus; either that isolated collections have escaped detection throughout the period of drainage, or that a part of the cavity has become sequestered by a contraction of its walls. Long continued observation after apparent cure is necessary to eliminate all sources of error.

I am in the fortunate position of having been able to complete the records of 123 cases of empyema, observed first by the Empyema Commission at Camp Lee, Va., and subsequently at General Hospital No. 12 at Baltimore, N. C. All of these patients were admitted

* From the Walter Reed General Hospital.

during the first six months of 1918, and as far as results are concerned, permit a comparison between the treatment of empyema by simple drainage and drainage combined with the Carrel-Dakin method. These cases naturally fall into two groups: Group 1 consists of 100 cases which had been treated by simple drainage immediately following diagnosis, and includes the cases up to the middle of April, 1918. Fifty-six patients were healed under this treatment; the empyema in the remaining forty-four became obstinate and persistently chronic until treated by the Carrel-Dakin method. In only ten cases was a thoracoplasty of moderate extent finally indicated. In Group 2 there were twenty-three patients who were admitted during April and May of 1918. They were treated by preliminary aspiration until the primary infection of the lung had subsided, and subsequently by thoracotomy and surgical solution of chlorinated soda.

* "Recurrences distant from sinus" includes undrained pus pockets resulting from multicocular empyema and lung abscesses. The mortality in Group A was high and these conditions were common in the necropsies which were performed. Of the total number of patients in Group B (twenty-four), only one died. This accounts for the high percentage under this heading.

Among the cases healed under simple drainage, fourteen, or 25 per cent., of the recurrences were encountered within eight months after the primary healing. The majority of these were discovered during the first or second months, either during routine examination or because of a rise of temperature. Ten of these cases, occurring at the site of the primary operation, were caused by the hemolytic streptococcus, the organism which was the cause of the original infection. The pus collections in the remaining four were found either at the apex of the pleural cavity or very high in the axilla, and probably were the result of isolation of a part of the original cavity by adhesions soon after operation. Although they were all purulent, living streptococci were found in only two; the others were sterile.

Among the sixty-seven cases healed under the Carrel-Dakin treatment, comprising the refractory empyemas of the earliest group as well as those in which

surgical solution of chlorinated soda had been used throughout, there were eight recurrences. Three of these occurred at the site of the previous operation; two of these were due to the hemolytic streptococcus, while the third was merely a collection of a small amount of clear, sterile fluid. Except for a lung abscess found at the angle of the scapula, the remaining five recurrences were at the apex of the pleural cavity. Bacteriologic examination revealed streptococci in two of these cases, *Staphylococcus aureus* in two cases, and one was found to be sterile pus.

A study of these recurrences is an interesting demonstration of the efficacy of the Carrel-Dakin treatment. The group treated by this method not only shows a higher percentage of perfect results, but also that the pus pockets which were discovered were usually at some distance from the original focus.

In discovering these secondary foci of pus there were two symptoms which proved to be of the greatest value: 1. The patients either never regained their normal weight or even lost weight in spite of the fact that they were continuously kept on high carbohydrate diet. In this connection it is interesting to note that in the cases of recurrence in two patients whose weight was above that recorded on admission to the army, the fluid was sterile. 2. In all cases of recurrence of a purulent nature, the pulse rate was always rapid and there was also a moderate fever. There were, in fact, two different types of fever present. Fever of a very acute nature was found most frequently in cases which

TABLE 2.—EFFECTS OF CARREL-DAKIN TREATMENT

	Total	Recurrences	
		No.	Per Cent.
Cases healed under simple drainage	56	14	25
Cases healed under Carrel-Dakin treatment	67	8	12

had been allowed to close before complete sterility was obtained; in these the febrile reaction was sharp and was usually accompanied by constitutional symptoms. In other cases a mild evening temperature of 99 to 99.5 F. was observed, especially when the pus pocket was at some distance from the primary empyema and was evidently of long standing. These points were well illustrated by the following histories:

REPORT OF CASES

CASE 1.—A patient admitted March 26, 1918, with bronchopneumonia developed a massive streptococcal empyema within the next two days. A costectomy was done, March 29. The wound healed after three months under simple drainage. When the patient was admitted to the hospital he weighed 160 pounds, and by the time the wound had healed he had regained all the weight lost during the acute stage of his illness. A routine examination, as well as a study of the roentgenograms made immediately after the wound had healed, revealed no abnormality other than a mass of adhesions and thickened pleura in the region of the scar. No further symptoms developed until July 27, when the temperature suddenly rose to 103, with malaise and all symptoms of a systemic infection. Physical examination and roentgenograms detected no change in the findings from those of the previous examinations. In the absence of other abnormal findings the chest was aspirated in the line of the old cicatrix; this revealed a small amount of pus which contained streptococci in pure culture.

CASE 2.—Jan. 2, 1918, a patient previously admitted with measles developed a bronchopneumonia and an empyema, which subsequently was treated by simple drainage. When the wound healed, April 15, the pulse rate averaged 120 and the afternoon temperature rose to 99.5. He was also 20

pounds underweight. In spite of a forced carbohydrate diet he gained very slowly. July 5, during a routine examination, the following findings were recorded: "The pulse rate, which is 104 even in the recumbent position, is markedly accelerated on exertion, and is accompanied by dyspnea. The hands are cold and moist. There is usually an evening temperature of 99 to 99.5 F. The expansion of the right chest is limited; the percussion note is resonant except over the scapula and between the inner border of the scapula and the vertebral column." When this dull area was aspirated, sterile pus was found. Subsequently the cavity was drained and healed under Carrel-Dakin treatment. At the time of his discharge in December, 1918, he had gained 4 pounds in weight.

COMMENT

The two histories just recorded illustrate the types most frequently encountered in the twenty-two recurrences I have observed. In the reaccumulations in the immediate vicinity of the first operation, physical and roentgen-ray examination often failed to differentiate between small collections of fluid and the thickened pleura which exists in practically every perfectly healed case. It is for this reason that the cicatrix was always aspirated first when there were symptoms of recurrence and the chest findings were apparently negative. Collections of pus in other parts of the chest could be definitely localized by physical and roentgen-ray examinations.

Small collections of fluid in the chest gave physical findings which varied according to their location. The most constant physical finding was an impairment of the percussion note; at times, however, it was impossible to differentiate between fluid and thickened pleura. It was also observed that areas of dullness which were entirely separated from the diaphragmatic dullness were usually due to fluid; those which merged gradually into the diaphragmatic dullness, particularly when associated with an abnormally high diaphragm, could be more readily accounted for by the cicatricial tissue which was present. There was some variation also in the character of the note elicited. In small sacculations there was moderate dullness instead of the flat resistance which is encountered in massive exudates. Tactile fremitus was diminished over the central area of fluid collections except in those located anteriorly over the right apex and along the hilum of the lung; in these areas increased fremitus and marked bronchial breathing were the rule. Auscultation was often unreliable and misleading, although it may be definitely stated that usually the respiratory sounds were distant. Areas of dullness in the axilla were always accompanied by diminished breath sounds and diminished vocal fremitus. In order to determine definitely the cause of these abnormal physical signs, it was found preferable to study them carefully in conjunction with stereoscopic plates before diagnostic aspiration was attempted.

Not only were stereoscopic plates preferable, but usually they were absolutely necessary. The plates were examined for abnormal shadows denoting the presence of pus pockets, for intrapulmonary lung markings, and for evidence of abnormalities in the pleura. The lesions at the apex were usually easily discovered because they produced a deep shadow, but a careful examination was always required to determine whether the pus collection was anterior or posterior to the lung. In the axillary shadows there was always difficulty in distinguishing between fluid and thickened pleura. Frequently, particularly when a cavity had closed after draining but a short time, a dense shadow

extended from the apex to the diaphragm along the axilla; with the gradual devascularization of the cicatricial tissue which causes this shadow, the plates became perfectly clear in this area and eventually resembled a partial pneumothorax. It was evident from many observations of this character, and from a comparison of the findings at secondary operations with the plates, that frequently thick scar tissue did not intercept the roentgen ray. Aspiration was often the only means of determining the nature of these abnormalities in the axilla. The pulmonary striae along the bronchi and their smaller branches were usually very heavy on the affected side. They could be readily followed outward from the hilum, and served as a guide in locating the border of the lung. In abscesses these lines radiated from the point of infection.

Two cases of lung abscess were observed at intervals during the period that these characteristic markings were developing. One, which was found just under the pleura at operation, had probably existed from the time of the initial bronchopneumonia. Both the lung and the adjacent pleura were irregularly thickened. The second case was kept under observation until dense radiating lines had formed through the involved lobe, and the pleura overlying the process showed evidence of inflammation. Both cases would have been confused with pleural pus collections if they had not given these characteristic plates and if numerous râles had not been heard on auscultation. It is certain that aspiration is the only way of definitely deciding the cause of many of the abnormalities found in the plates.

The treatment of these recurrences depended entirely on the character of the fluid found. When it was clear and sterile, aspiration was all that the case required. With the exception of one which was completely evacuated at the diagnostic puncture, all the purulent fluids were drained by thoracotomy. Cases which have shown a recurrence at the site of the primary operation frequently have recurred again in spite of the greatest care exercised in treating them; in many of these cases of second recurrence there were small pieces of necrotic bone in the sinuses. The care of these cases required the closest cooperation between the surgeon, the internist and the roentgenologist.

Curative Workshop and Vocational Apprenticeship System.

—A plan has been developed by the federal board for vocational education, with the cooperation of the commandant of the Navy Yard and the commanding officer of the Naval Hospital at Norfolk, Va., for the establishment of a combined curative workshop and subsequent vocational apprenticeship system, which may be used as a standard for all Navy yards. The general features of the plan as outlined by the board are as follows: ambulant convalescent patients may be given therapeutic training through appropriate operations and exercises in the shops of the Navy Yard, but under conditions which duplicate actual productive shop conditions. The federal board's representative advises with the men and with the surgeon in charge. These two men decide on appropriate work. In the office of the yard is another representative of the board, a coordinator, who receives the prescription and arranges for training under a competent mechanic who has also been trained as an instructor by the federal board. Men having completed their period of hospital training and therapeutic training may continue to receive vocational training in a wide variety of Navy Yard occupations. Neither in the therapeutic phase nor in the vocational phase is it assumed that men will necessarily eventually become employees of the Navy Yard. The work is carried on at the expense of the federal board, with the cooperation of the Navy Yard authorities.

THE THERAPEUTIC ASPECT OF BLOOD
TRANSFUSION*

LESTER J. UNGER, M.D.

NEW YORK

The recent wave of enthusiasm for transfusion was initiated by the introduction of simplified methods for transferring blood, the elimination of dangers, and an increasing appreciation of the therapeutic value of the procedure. The nearer one approaches giving blood as it exists within the vessels of the donor, the nearer one attains ideal conditions. Numerous procedures have been suggested to render the technic of anastomosing vessels less difficult; but none have survived the practical test, so that indirect methods have gradually taken their place. These are of two types; those supplying whole unmodified blood, and those which add an anticoagulant. The first group is represented by the method of Kimpton and Brown,¹ by that of Lindeman,² and by the one³ described by me in this journal some years ago.⁴

These methods mechanically overcome the technical difficulties of direct transfusion. However, the problem has also been attacked by rendering the blood non-coagulable by the addition of small quantities of sodium citrate.⁵

The relative merits of unmodified blood and of blood thus modified by means of sodium citrate is one of the points of active interest in connection with this subject. As is well known, the latter method has recently gained considerable vogue and, indeed, by some is claimed to render other methods of transfusion unnecessary. From my point of view, transfusion of unmodified blood cannot be so lightly set aside.

One of the differences between unmodified and citrated blood is manifested clinically by the more frequent occurrence of reactions with the latter method. Drinker and Brittingham⁶ state that, after citrate transfusions, febrile reactions occur in 60 per cent. of cases and a chill in 57 per cent. In my series of unmodified blood transfusions, febrile reactions have occurred in about 10 per cent. and a chill in about 3 per cent. This difference in the number of disagreeable reactions is due to an abnormal condition

of the blood platelets and the red cells in the citrated blood. It has been shown by Novy and DeKruif⁷ that blood acquires toxic properties in direct proportion to the path it has traveled toward coagulation. Even though it does not absolutely coagulate, processes take place within it as soon as it is poured forth from the vessels which change its nature and render it less suitable as a body fluid. These coagulative changes have been shown by Drinker and Brittingham to be associated with the platelets which become abnormal as soon as they leave the vessel. They write:

The grade of abnormality of these elements depends to some degree on the extent . . . of the handling which they are compelled to undergo in the varied methods of transfusion. . . . There is no practical method for citration of the large quantities of blood needed for transfusion which certainly prevents the early changes of coagulation. The methods in use simply arrest the process. The truth of this statement will be testified to by many who have used the citrate method with complete coagulation of the blood at a critical point in the transfusion.

Methods for using whole unmodified blood can probably be similarly criticized, though to a less extent. Here there is infinitely less handling, and coagulation cannot have progressed so far since the blood is out of the body a shorter period. By the method described above,³ the blood is out of the body about five seconds.

Drinker and Brittingham have also shown experimentally that "the mere addition of a dose of sodium citrate" to red cells induces slight abnormality, as evidenced by an increased fragility and an increased tendency to hemolyze. The corpuscles are damaged by sodium citrate operating as a specifically harmful substance. This is of particular importance when transfusion is performed in hemolytic diseases.

These studies seem to show, what *a priori* would seem to be most likely, that from a biologic point of view the delicate blood tissue must be altered in the carrying out of a transfusion of citrated blood. For diseases in which blood is indicated for itself, that is, when it is required as a tissue, as in the various anemias, especially when the disease is hemolytic in nature, there can be no question as to the relative merits of unmodified blood which runs almost from vessel to vessel and that which has been handled, chemically altered and allowed to remain for an indefinite length of time outside of the body. The transfusion of unmodified blood is the procedure of choice. It must be admitted, however, that the technic for giving citrated blood is simple, and that therefore in cases of hemorrhage, in which the purpose is not so much to supply normal blood for pathologic blood as to furnish the impoverished circulation with an adequate supply or to bring about cessation of hemorrhage, citrated blood may serve as a substitute.

It has long been recognized that unless the donor and patient belong to the same iso-agglutinin group, iso-agglutination and isohemolysis are possible dangers to the patient. Agglutination frequently occurs with hemolysis, but hemolysis is always associated with or preceded by agglutination. Therefore, if tests are made which eliminate the possibility of agglutination, hemolysis is also automatically guarded against. Although any of the recognized methods for testing this phenomenon may be employed, the microscopic

1. Kimpton, A. R.; Boston M. & S. J. **178**: 351 (March 14) 1918.

2. Lindeman, Edward; Simple Syringe Transfusion with Special Cannulas, *Am. J. Dis. Child.* **6**: 28 (Feb.) 1913.

3. The mechanical principle involved in the instrument used in this method is the establishment of two channels by means of which a record syringe is automatically connected alternately with a vein of the donor and then with one of the recipient. At the same time that the record syringe is connected with the donor for the aspiration of blood, a syringe with saline solution is connected with the recipient, and vice versa. It is this immediate and continued flushing with salt solution of that channel through which blood is not passing that insures freedom from clotting. The technic is as follows: Alongside the instrument which has been fixed to a table, the arms of the patient and the donor are placed. The tubes leading from the instrument are connected to the cannulas after the latter have been inserted through the skin into the recipient's and the donor's veins. A record syringe is then inserted into the instrument, and blood is aspirated. When the syringe is filled, the stopcock is turned and then the blood is injected. Simultaneously saline solution is forced through the channel which is not being used for the aspiration or injection of blood. This procedure is continued until the desired amount is transfused. In order to prevent clotting, a stream of ether is played on the barrel of the record syringe while it is being filled with and emptied of blood. In this way only one record syringe is required, regardless of the amount transfused.

methods recommended by Moss⁸ or Lee⁹ and by Rous and Turner.¹⁰ are the simplest and quickest. By the method of Moss, mixtures of the patient's cells with Groups II and III serums are made and examined under the microscope. In this way the patient is placed in his proper group.¹¹ The proper subject is selected from a list of donors whose groups are known and whose Wasserman test is negative.

When standard Groups II and III serums are not on hand and when donors are not so available or are not classified according to groups, the more direct method of Rous and Turner¹² is of value. According to this method the blood of each donor is tested against that of the recipient without first determining its respective group. If no agglutination takes place, the donor is suitable as far as iso-agglutination and iso-hemolysis are concerned.

In New York there is a group of professional donors who have been used repeatedly, indeed, too often. The opportunity was therefore presented to observe the effect on the donor of giving blood repeatedly for transfusion. This is a study of clinical interest simulating conditions in which hemorrhage occurs from time to time in considerable amounts, and seems therefore worthy of greater attention than it has been heretofore granted. Within a few days, signs of secondary anemia appear which will be recovered from entirely provided sufficient time is allowed to elapse. If, however, the donor submits to repeated and frequent transfusions, the anemia may become intense. Two donors had a hemoglobin of only 55 per cent., in spite of the fact that four and eight weeks had elapsed since their last transfusions. One of these men had been a donor for four and one-half years and had given blood on fifteen occasions. Because of the anemia he went to work at a mountain summer resort where he had plenty of food and fresh air; but after three months his hemoglobin was only 67 per cent. For the succeeding three months he received arsenic and iron (six months after his last transfusion), and his hemoglobin rose to 98 per cent.

The statistics relating to another donor are interesting and seem worth recording as showing how much the body can withstand in this respect: At the time of this man's first transfusion, he weighed 175 pounds. Six and a half years later he weighed 201 pounds. During this period he underwent sixty transfusions, donating about 50,000 c.c. of blood, for which he had received \$1,700. This man, therefore, had lost his total blood volume ten times during this period. His hemoglobin, taken nine weeks after his last transfusion, was 70 per cent., otherwise he was apparently in good health.

After donors have given up blood repeatedly over a period of years, certain changes result. There is a definite secondary anemia which in some cases may be intense. There is poikilocytosis and anisocytosis of various degrees. In no case were nucleated reds observed. The leukocytes are increased in number, varying between 10,000 and 14,000. The differential count is about normal. The anemia is probably due to the fact that sufficient time is not allowed between transfusions for the rise to normal of the hemoglobin and red blood cells. In one case observed, this anemia was not permanent and the donor recovered from it. This fact is of practical importance because in pernicious anemia in which repeated transfusions are necessary, a particular donor often seems to be able to institute remissions when other donors fail.

DOSAGE

With blood, as with other therapeutic measures, the amount given is a factor in determining the result. A donor can with safety supply one quarter of his blood volume. Just how much of this a patient should be given is dependent on various factors. For infants the usual dose should be from 80 to 150 c.c. For adults, from 800 to 1,000 c.c. This amount, of course, varies with the weight, the condition of the patient's heart and lungs, and the disease for which the transfusion is being performed.

Overtransfusion from the donor's standpoint is evidenced by an increase of the pulse and respiratory rates, repeated yawning or deep sighing. Changes in the rhythm of respiration may occur before a change of the pulse rate. If these symptoms appear, the transfusion should be discontinued. Pallor and sweating are occasionally followed by collapse. From these symptoms he will quickly recover if the transfusion is discontinued.

As regards the patient, hypertransfusion is more serious. This may lead him to complain of precordial distress, headache, backache, or pain in his legs. A more important sign, however, is a short, sharp cough. If the transfusion is continued, the cough will be repeated. The cough, when it does appear, occurs irrespective of the rate at which the blood was transfused. One should not transfuse more than 200 c.c. after the first cough. In only one case has this sign been disregarded. In this instance 500 c.c. were transfused after the first cough. This was the only case in my series in which transfusion was complicated by hypertransfusion; pulmonary edema developed, and the patient died.

INDICATIONS FOR TRANSFUSION

The indications for transfusion¹³ are: (1) hemorrhage; (2) diseases of the blood; (3) toxemias; (4) infections; (5) shock, and (6) general debility.

1. *Hemorrhage*.—This is one of the conditions in which blood transfusion is the ideal form of treatment. It serves not only to replace loss of blood but also to check actual bleeding. In acute hemorrhages, the results are naturally more brilliant than in less fulminating bleeding. In about 85 per cent. of the cases of acute hemorrhage, bleeding can be stopped by one transfusion.

2. *Diseases of the Blood*.—In secondary anemia, the results are satisfactory, provided the primary

10. Rous, Peyton, and Turner, J. R.: A Rapid and Simple Method of Testing Donors for Transfusion, J. A. M. A. **64**:1980 (June 12) 1917.

11. If the patient's cells are agglutinated both by Group II and Group III serums, the patient is in Group I; if they are agglutinated by neither II nor III, he is in Group IV; if by III serum and not by II, he is in Group II; and if by II serum and not by III, he is in Group III.

12. The following simplifications of the method of Rous and Turner have been satisfactorily employed by me: In a pipet used for counting leukocytes, one part of 10 per cent. sodium citrate and ten parts of the patient's blood are mixed. A similar specimen of the donor's blood is collected. From these specimens, by means of a third pipet, are mixed nine parts of the donor's blood to one part of the patient's, and also one part of the donor's to nine parts of the patient's. A drop of each of these mixtures is put on a slide, a drop of physiologic sodium chloride solution is added, a cover glass is applied, and examination is made under the microscope. Any clumping, not coagulation, is agglutination, and this donor should not be used. Usually the clumping appears immediately, but it is wise to observe the mixture for fifteen minutes.

cause is removed. In pernicious anemia, transfusion yields results superior to any other mode of therapy. Frequently it acts as a lifesaving measure by initiating the onset of a remission. There is no evidence, however, that the disease can be permanently cured in this way. Nevertheless, by repeated transfusions, remissions can be effected and the lives of some patients made useful for years. In such cases, if possible, the same donor should be successively employed. The amount of blood does not seem to be the determining cause of a remission. Small amounts have often been of as much value as large amounts. When transfusion is successful, the increase in strength and appetite is very striking. It will relieve the anemia and the symptoms secondary to it—dyspnea, palpitation, mental symptoms, etc. In no instance did it lead to an increased secretion of hydrochloric acid by the stomach. If transfusion is repeated because the first one failed to bring about a remission, a different donor should be employed, and this procedure should be continued until, if possible, the desired effect is achieved. In such cases, retransfusion should be resorted to before all the ground that has been gained is lost. In certain cases, however, even this procedure is of no avail.

Hemophilia is not cured by transfusion; but for the bleeding of hemophilia, it is practically a specific. It will succeed when all other methods fail. Valuable time should therefore not be lost in attempts to control bleeding by other methods, since we have at our command a specific that will not only control the hemorrhage but also replace the lost blood.

In purpura hemorrhagica, the results of transfusion are only fairly good. Repeated transfusions are often necessary to control the bleeding.

In acute lymphatic leukemia, only a temporarily favorable effect can be secured by transfusion, even though we withdraw a large amount of blood by phlebotomy and make use of a massive transfusion obtained from two donors, or employ repeated transfusions, or carry out transfusions very early in the disease.

In bleeding of the new-born, transfusion is a specific. An almost exsanguinated infant, too weak to cry and in a dying state, is transformed immediately into an apparently healthy, rosy and crying baby. As in hemophilia, it will save the lives of those who are not helped by subcutaneous injections of serum or blood. Temporizing by using less effective measures may cost the baby's life. This is especially true in cases of melena neonatorum, which are the most serious because we do not know just when the hemorrhage began or how much internal hemorrhage is taking place. Just as soon as the diagnosis of bleeding from the stomach or the bowel of the new-born is made, transfusion should be performed.

3. *Toxemia*.—Transfusions have long been used in a limited number of types of toxemia. It is in this group that the indications ought to be enlarged, especially in the toxemia of pregnancy and in toxemias associated with acute infections, such as pneumonia and typhoid fever.

4. *Infections*.—In localized pyogenic infections, transfusion will increase the patient's vitality and aid in overcoming the infection.

In bacteremia when the source of the organisms can be found and eliminated, the results are excellent, as in cases of sinus thrombosis following mastoiditis in which the jugular vein has been ligated. In post-

partum sepsis only one patient out of about twenty recovered; the others showed merely temporary improvement.

5. *Shock*.—Transfusion is at times valuable in shock. It seems possible that the nearer the transfusion approaches the advent of the shock, the more likely it is to be successful.

6. *General Debility*.—Transfusion should be used preliminary to operations as a supporting measure, and thus lessen the postoperative mortality. In debilitating conditions, such as inoperable carcinoma and pemphigus, it will improve the patient's general condition and prolong life.

SUMMARY

There is a far greater number of reactions following transfusions with citrated blood than with unmodified blood. This is due to alterations in the blood cells. The platelets undergo early coagulative changes. Sodium citrate acting as a harmful foreign substance renders the red cell more fragile and more easily hemolyzed. This undesirable result is of especial importance in hemolytic diseases.

Transfusion of whole unmodified blood is the procedure of choice when blood is required as a tissue. When it is wanted merely to replenish an impoverished circulation with an adequate supply, citrated blood may serve as a substitute.

For the selection of donors, a simplified and rapid microscopic method, such as that suggested,¹² is desirable.

Repeated withdrawal of blood for transfusion may produce in the donor an intense secondary anemia with an increase in the leukocyte count. In the illustrative case reported, sixty transfusions were performed within a period of six and one-half years, with the removal of fifty liters of blood.
